Academy Street, Fitchburg, Mass. Constructed with "Tarvia X". One of the many streets constructed in Fitchburg during the last ten years with Tarvia, some with grades up to 14 per cent.

How roads wear out—

MACADAM roads disintegrate by various processes. Automobiles destroy the surface, pulverizing and loosening it so that it blows away in the form of dust. When the top coat of screenings is thus destroyed, the road has lost its roof, and water, instead of being shed quickly to the gutters, penetrates into the lower layers of larger stone and does endless damage.

Under heavy loads ordinary macadam undergoes a certain amount of internal movement which is very destructive. The stones below the surface, grinding against each other under great pressure, exert a mutually abrasive effect, resulting in a general disintegration and breaking-down. The modern way to protect roads against such wear is to bond them with Tarvia.

Tarvia is a dense, viscid compound of coal tar. It fills the voids between the stones and forms a tough, plastic matrix. On the Tarvia surface thus formed automobile wheels do no damage, since the tenacity of the Tarvia is great enough to resist the traffic.

Used in the interior of the road, Tarvia keeps the stone in its proper position and prevents internal shifting, rubbing and grinding These two results of the use of Tarvia bring about great economies in maintenance.

A tarviated road lasts so much longer and needs so little care that the cost of the Tarvia is more than compensated for.

Speed!

Faster!

Open the throttle—advance the spark—tramp on her tail—one minute to make it!

Easy enough with a Continental, when you want to get there, and get there quick.

Continental Motors

Yet the flash of swiftness, or the mad onrush that crashes through the smoke welter of the speedway is really not the speed that counts; for it is a fever, not an excess of vitality.

Continental speed (and this is true of every one of 1914's tens of thousands of Continentals) is that healthy speed which endures; which, as the work calls for it, be it 40 or 50 or 60 or 70 miles an hour, can be depended on for minutes, hours, days, weeks and years.

For Speed is the daughter of Power. And *unbounded power* "is the dominant characteristic of the Continental Motor"—power within bounds, never creeping near the danger mark, bringing no risk.

Continental speed and power are attained by superior theory, put into better practice. Continental crankshaft bearings are ground to 95% of bearing surface, smoother than a mirror, pistons are balanced to a pennyweight; connecting rods are lightened to a mathematical niceness; valves are seated-in with a faultless exactness; cylinders are polished to a flawless luster.

The foremost technical experts of America and Europe, men of the Continental and allied firms, working for ten years, have made Continental speed possible.

Let Continental speed guarantee satisfaction in the car you plan to own

NEW, REVISED AND ENLARGED EDITION
SHOWING ALL RECENT IMPROVEMENTS

THE MODERN GASOLINE AUTOMOBILE

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice. Latest and Best Treatise
Over 800 (5½x8) Pages—*11 Large Folding Plates*—575 Illustrations

PRICE $2.50

The latest and most complete treatise on the Gasoline Automobile ever issued. Written in simple language by a recognized authority, familiar with every branch of the automobile industry. Free from technical terms. Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile. The information is up-to-date and includes, in addition to an exposition of principles of construction and description of all types of automobiles and their components, valuable money-saving hints on the care and operation of motor cars propelled by internal combustion engines

TO THE 1914 REVISED EDITION

Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four-wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive. The subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearings, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, etc., have been added to bring the work thoroughly up to date.

The book tells you just what to do, how and when to do it. Nothing has been omitted, no detail has been slighted. Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc., have been discussed comprehensively. If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is a book you cannot afford to be without.

**THIS BOOK IS SUPERIOR TO ANY TREATISE PUBLISHED
IT IS RIGHT UP-TO-DATE AND COMPLETE IN EVERY DETAIL**

MUNN & COMPANY, Inc., 361 Broadway, New York

Machines and Mechanical Devices.

(Concluded from page 374.)

justable firing mechanism for submarine mines, by which the point of explosion of the mine on the side of a ship can be determined, and which can be examined at any time for regulation and keeping in repair.

AUTOMATIC TIME CONTACT SWITCH.—H. B. Meier, 222 Madison Ave., Port Chester, N. Y. This inventor provides a casing for a clock, said casing having a door closing the same so as to exclude dirt or other substances or conditions which might interfere with the proper operation of the clock mechanism, and said door serving, when closed, to make connection between the two parts of an electric wire, but so arranged that when the door is open, said parts are separated so that it will be impossible to complete a circuit from the battery until the door is again closed.

SANITARY TOWEL AND SOAP SERVICE.—C. H. Parvin, 147 Fern Ave., Collingswood, N. J., and M. L. Snyder, Wyncote, Pa. Address the former. This invention relates to automatic vending mechanism, and has particular reference to means for dispensing sanitary towels and soaps in public places. It delivers a quantity of soap, permits withdrawal of a certain amount of toweling of any suitable nature, and the operation of the mechanism for the purpose of initiating the movement thereof through the use of a coin or check serving to deliver the soap.

GATE LATCH.—D. Loudenslager, Rising City, Neb. This latch member is mounted on a gate post in such a manner that a catch of suitable device on the gate itself will, on closing, strike the latch and cause the latter to yield to permit the catch to pass to a position where the latch will automatically grip the catch and hold the gate closed.

ROAD SCRAPER AND SMOOTHER.—G. E. Tucker, Springwater, N. Y. The purpose here is to provide a structure which may be variously adjusted for causing the smoothing or scraping members to act all together or successively, and at any desired angle to the direction of travel of the device so that the road may be operated in substantially any desirable way according to the circumstances.

FIRING APPARATUS FOR MOORED TORPEDOES.—G. E. Elia, Rome, Italy. This invention relates to a firing apparatus for moored torpedoes or mines of the spherical or cylindrical type, and the firing mechanism relies for its actuation upon the well-known fact that a spherical or cylindrical torpedo acquires rotative motion from a vessel coming into contact therewith.

LADDER.—M. H. Hoffman, Box 83, Masontown, W. Va. This ladder is especially adapted for use on uneven ground, and wherein each of the stiles is provided at its lower end with an extension, capable of being moved longitudinally with respect to the stile, to lengthen the stile, and wherein mechanism is provided for operating the extensions simultaneously in opposite directions.

VENDING MACHINE.—S. C. Gilbert, Jackson, Ohio. Mr. Gilbert's invention relates to coin-controlled vending machines, and particularly machines for vending peanuts in packages. It is a design of the invention to provide an improved machine of the indicated character having a series of separate units, including carrying members and driven elements for actuating said members.

MACHINE FOR COVERING ELECTRIC CONDUCTORS.—E. H. Cook, care of Miss A. M. Harrison, 99 Keap St., Brooklyn, N. Y. The present invention relates to a machine for covering a wire or conductor with insulating material, and has more particularly reference to an improved structure for applying asbestos or the like to wire or conductor.

STRIP GUIDE FOR SEWING MACHINES.—F. L. Corson, 87 Winter St., Rochester, N. H. The device, which is preferably attached to a sewing machine, holds the ribbed portion of the canvas between the sides of the canvas in position, while it spreads the sides of the canvas, and holds them against the inner sole, while it is sewed thereto.

ATTACHMENT FOR STEREOPTICONS.—H. A. Gottlieb, 129 E. 59th St., New York, N. Y. The invention provides a magazine for holding lantern slides, with co-operating parts for successively permitting the slides to be positioned in front of the condensers, such operation, together with the consequent operation of taking care of the exposed slides, being under the control of the operator.

Prime Movers and Their Accessories.

ROTARY ENGINE.—E. F. Girod, P. O. Box 452, Monroe, La. An object here is to provide a novel form of device which will rotate in either direction by merely turning the valves of the intake and exhaust pipes. The invention provides a rotary engine having a novel form of valve operating mechanism, and a rotary engine having a pair of pistons acted on alternately at points 180 degrees apart.

Railways and Their Accessories.

STREET INDICATOR FOR CARS.—F. H. Webster, Marvel, Ark. This invention has reference to street indicators, and more particularly to street indicators carried upon cars, for the purpose of disclosing, to persons occupying the cars, the names of the streets, in successive order, as the cars travel along.

Pertaining to Vehicles.

AUTOMOBILE STARTER.—H. H. Moseley, 112 [illegible] The primary object of the invention is to provide an efficient [illegible] of operation by the [illegible] seat to impart initial [illegible] to the crank shaft of the motor for starting the latter, thus obviating the necessity of the chauffeur alighting from the car.

RADIATOR.—R. H. [illegible] Union St., Brooklyn, N. Y. This invention relates preferably to the type designed to remove the heat from the cooling water of the engine of an automobile or other vehicle, and the primary object thereof is to produce a radiator which will be of simple and practical construction, and at the same time operate with the highest possible efficiency.

ROTARY MEASURING DEVICE.—H. C. Spedden, Grangeville, Idaho. This instrument is for use in connection with vehicles for measuring the distance a vehicle travels on an imaginary horizontal line irrespective of the contour of the road on which the vehicle travels. While useful in this particular application it may be employed to make linear measurements generally.

LIMBER PIN FOR MINE SKIPS.—C. H. Sawyer and J. Bowditch, Newcastle, New South Wales, Australia. This improvement relates to devices for coupling a mine skip or like vehicle to animal draft gear, and has been designed to provide for that purpose an improved limber pin of simple and strong construction adapted to effect such engagement with the draw bar hook of said vehicle that the same may not become detached and withdrawn during progress of the vehicle, but further may be manually disengaged with facility.

AUTOMOBILE WRENCH.—P. S. Merrill, 185 Main St., Waterville, Maine. The object of invention No. 1,092,071, is to provide a simple, inexpensive and strong wrench combining the features of a monkey, pipe, and ratchet wrench designed for use in reaching any nut or bolt at any angle. This is obtained by providing a shank having an extension in the shape of a sector, a jaw pivotally mounted on the shank and associated with the sector, a second jaw slidably and adjustably mounted on the shank and co-operating with the first jaw and a handle adjustably mounted in the sector whereby the wrench is manipulated.

RESILIENT WHEEL.—P. F. Marcante, 429 Cedar St., Allentown, Pa. An object here is to provide a spring wheel structure in which the various springs are retained under a predetermined tension, and are all caused to act in unison when there is a sudden jar or load placed on the wheel whereby lighter springs may be used, as all the strain of a sudden weight or jar does not come under a single spring.

SNOW PLOW.—W. L. Stadig, St. Francis, Maine. This invention provides co-acting means for taking up the snow and causing it to be raised and deflected to the side of the road. It removes snow from highways, logging roads, and the like. It provides means associated with the rotary elements, and adapted to gather the snow to the latter, the said means being arranged for adjustment to the road level, or to leave a "comb" in the road center.

ROAD WAGON.—A. Macdonald, Bundarra road, Inverell, New South Wales, Australia. The present invention has been devised to provide a combination four wheeled farmer's wagon and tip-dray so arranged that the rear portion of the wagon may be tipped and is detachable for separate use as an ordinary two wheeled tip-dray.

SPRING WHEEL.—R. Fourchy, 211 Post Office, Kansas City, Mo. This invention refers to spring wheels for vehicles and has reference more particularly to the resilient connection between the rim and the hub, said connection comprising a plurality of independent resilient units located between the spokes and intermediate the rim and the hub.

LAMP MECHANISM FOR AUTOMOBILES.—R. C. Browne, Lock Box 257, Cons, Ill. This invention provides a lamp mechanism controllable automatically by the steering wheels and parts connected immediately therewith so that when the steering wheel is turned the lamps of the vehicle are turned to correspond with the angular direction in which the vehicle is turning.

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

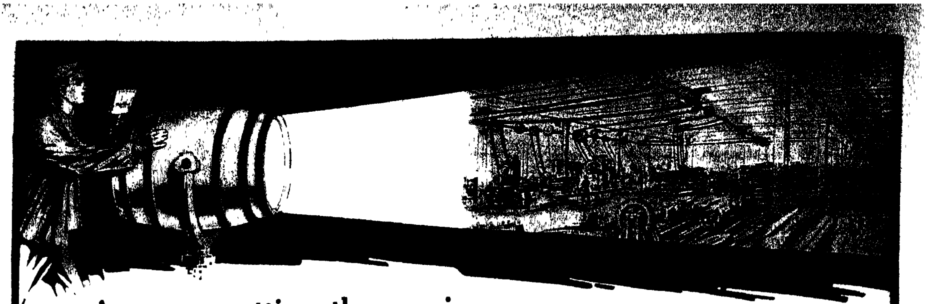
Price 10 Cents
$3.00 A Year



Are you getting the maximum amount of daylight in your plant?

Or is a large percentage absorbed, swallowed up, *wasted*, in your ceilings and walls? The difference can be reduced to dollars and cents—in your lighting bills, the efficiency of your employees, the quality of your product.

Rice's Mill White will fill your factory with sunshine. It will reflect every ray of your natural or artificial light down on to your machinery and into the dark corners of your plant. Its glossy, tile-like surface will not absorb light or collect dirt, germs and odors like a flat paint. It can be washed like tile.

Rice's Mill White will not scale and require frequent renewals like a cold-water paint. It will not "alligator" and crack under the jar of machinery like a varnish paint. It flows easily under a 4-inch brush; two coats equal three of lead and oil. *It stays white longer than any other gloss paint.*

Rice's Mill White made a trade name of the words, "Mill White." None of its imitations has its elastic, permanent qualities. No other paint manufacturer can use the Rice process. Rice's Mill White for ten years has proved itself unequalled for illuminating power, sanitary qualities and low ultimate cost.

Rice's Granolith

A tough and elastic permanent finish for concrete walls. Becomes a part of the cement to which it is applied. One coat sufficient unless a gloss is desired. Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White Paint giving a tile like enamel finish at no more expense than lead and oil paint.

For Concrete Surfaces

Rice's Mill White is sold direct from our factory, in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover,

The Modern Gasoline Automobile

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice. Latest and Best Treatise

Over 800 (5½ x 8) Pages 11 LARGE FOLDING PLATES 575 Illustrations

Price $2.50

The latest and most complete treatise on the Gasoline Automobile ever issued. Written in simple language by a recognized authority, familiar with every branch of the automobile industry. Free from technical terms. Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile. The information is up-to-date and includes, in addition to an exposition of principles of construction and description of all types of automobiles and their components, valuable money-saving hints on the care and operation of motor cars propelled by internal combustion engines.

TO THE 1914 REVISED EDITION

Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four-wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive. The subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearings, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, etc., have been added to bring the work thoroughly up to date.

The book tells you just what to do, how and when to do it. Nothing has been omitted, no detail has been slighted. Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc., have been discussed comprehensively. If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is a book you cannot afford to be without.

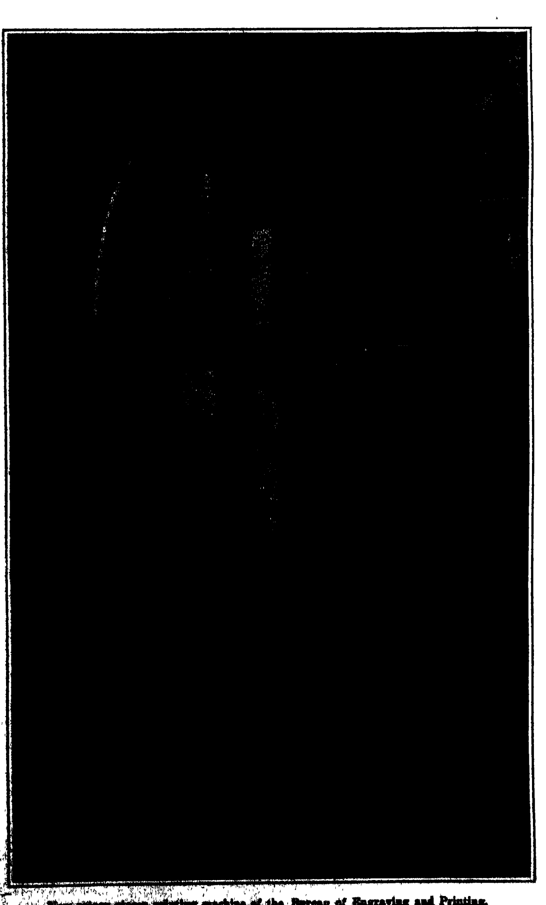
New Stamp Printing Machine of the Bureau of Engraving and Printing

WHEN a man purchases a penny postage stamp, he is quite apt to overlook the cost of producing that stamp and think that the whole of his investment will go toward paying the expense of sending his missive to its destination. To be sure, the cost of production is almost negligible when calculated for a single stamp, but when he learns that about forty million stamps must be printed daily to supply the demands of our letter writing population, he realizes that the annual bill for printing postage stamps amounts to a very considerable figure.

The manufacturing cost has been reduced materially of late by the inventions of Mr. Benjamin R. Stickney, mechanical expert and designer of the Bureau, working under direction of Mr. Joseph B. Ralph, Director of the Bureau of Engraving and Printing. As postage stamps are printed from engraved plates, the ordinary high-speed printing processes are not applicable to them. Ordinarily, it is necessary to moisten the paper so that it may readily be pressed into the engraved lines of the plates to pick out the ink that fills them. The common press cannot exert sufficient pressure upon the paper to make good prints if the paper is dry. And so up to a recent date all the paper had to be moistened by hand, which was a slow and costly process. Then about four years ago Mr. Stickney invented a machine for wetting paper, and he followed this up two years ago with a stamp printing machine that would print on a roll of dry paper. Not only did this eliminate the bothersome operation of wetting the paper, but it reduced the clerical work of keeping track of the separate sheets on which the stamps were printed; for now they were printed on continuous rolls at the rate of 12,000 postage stamps per minute.

This high-speed machine has since been further improved, and it now appears as in the accompanying engraving. The paper is fed from the drum shown in the foreground. It passes up over rollers, and then down between the feed roller and the printing cylinder. Here an enormous pressure is put upon the dry paper, which forces it into every line of the engraving. At the back of the cylinder is the inking font, below which are metal fingers, covering a space about 8 inches wide and extending the full length of the cylinder. The fingers vibrate lengthwise on the cylinder. A wiping belt vibrates with the fingers, but at the same time moves forward, wiping the surface of the cylinder as clean, as if the work were done by hand.

In Mr. Stickney's first machine, the paper passed from the printing cylinder over a series of electrically heated rollers to dry the ink. In the present machine the strip of stamps passes upwardly, and, in the language of the Bureau of Engraving and Printing, "loops the loop" over a long curved copper plate heated by electricity, as may be seen in the [illegible] of [illegible] engraving. [illegible] then passes under a roller at the extreme lower front and proceeds rearwardly to the gumming font. After being automatically gummed, it passes into a steam-heated drying shaft about 25 feet long. From the drying shaft it enters the perforator and slitter and is discharged from the machine in long strips that are coiled up like ribbon.



New rotary stamp printing machine of the Bureau of Engraving and Printing.

An Underground Canal

A PIECE of engineering work of considerable scope in the shape of an underground canal is now going on in the south of France, the object being to complete the waterway across the country. Starting from Havre, boats can pass by the Seine, the Saone and the Rhône with their junction canals as far as Lyons and from there to Arles, but access to the Mediterranean is prevented on account of the fact that the Rhône is no longer navigable after that point. Work is now carried out upon a canal which will make connection from the Rhône at Arles to Marseilles, of about fifty miles length. On the course lies the large lake known as Etang de Berre, which will be reached by open canal. From the lake to Marseilles a mountain chain cuts off the way, so that the canal must be run in tunnel from here to the sea. As the underground canal needs to be of large section, and is some 4½ miles long, this represents quite an undertaking, and will use most of the $15,000,000 allotted for the canal enterprise. A circular arch section is used, with narrow towpath on each side, the width of the section being 73 feet and height 51 feet, so that its section will be eight times that of the Paris subway. The canal itself occupies a rectangular section 10 feet deep and 60 feet wide. At present this work is under way, and will represent some 2,000,000 cubic feet of rock excavated and emptied into the sea. Electric cables bring over 2,000 horse-power for the drills and other machines, besides the electric locomotives for spoil trains. The canal will be on sea level as far as Arles, with locks from thence to the Rhône level. Great economic consequences are expected, and the above-mentioned lake will form an inland sea depending on Marseilles, and its shores will no doubt be covered with maritime and industrial establishments. Marseilles will now become a river port as well as a seaport, and Lyons will connect with the Mediterranean.

How Paris Disposes of City Waste

QUITE an elaborate system is soon to be put in operation for disposing of the great amount of household waste of the city of Paris. At present there are used 730 large wagons of 180 cubic foot capacity, 1,500 horses, and 3,000 men, and the annual amount is estimated at 900,000 tons, or 2,600 tons per day. On the old system, Seine flats took the material either to sea or river points, or it was transported to the surrounding country. But a modern method is to be organized which involves the use of electric trucks and a system of five large consuming plants in the suburbs at different points around the city. Two of the plants are now in operation, and the electric trucks are being introduced by degrees. At the St Ouen consuming works all is laid out on approved ideas, and the electric trucks discharge automatically into a pit 300 feet wide, at the bottom of which is a set of belt conveyors for taking the material either direct to the grinding mills or to the consuming furnaces. Other conveyors take the material and discharge it into silos above the furnaces. After combustion at about 1,000 deg. Cent. there is left a residue resembling slag or clinker. Suitable means are provided for taking the clinker to a mill, where it is ground and mixed with lime so as to make up bricks. Hot gases from the furnaces serve to heat the boilers and supply steam turbines for producing not only all the power needed on the premises, but a considerable amount sent outside. As much as 900 tons of waste is handled per day.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Plans of the Cup Defenders

WE direct attention to the unusually complete plans of the cup-defenders of the "America's" Cup, which were published in the last issue of the SCIENTIFIC AMERICAN. This material is presented in recognition of the widespread interest which is aroused whenever a challenge reaches this country for a series of races for the greatly coveted yachting trophy.

In no previous contest has so much informing data been available thus early in the season. It has been withheld from publication until the construction of the yachts had reached a stage at which it was too late to make any alterations, either in hull or sail plan, based upon "what the other fellow was doing."

The three designers, Herreshoff, Gardner, and Owen, have worked absolutely independently of each other—and the result has been the production of three widely different yachts, and a complete covering of the field. Nicholson, the designer of the "Shamrock IV," is "up against" a strong combination, and if the visitor, after crossing three thousand miles of ocean, and competing in unfamiliar water, can win the cup—so much the greater will be his glory!

The Plight of the Railroads

LET us be fair to the railroads. They are asking the Government to permit them to make a moderate increase in rates, basing their plea upon the ground that the increase both in wages and in the cost of materials of late years has been so great as to make it necessary for them to increase their freight rates if they are to maintain their systems in good condition and return a reasonable profit to the stockholders.

Is this request a reasonable one? It is our belief that a review of the facts would justify the Interstate Commerce Commission in permitting many, if not all, of the railroads which have preferred the request to make the desired increase Every one knows that the cost of labor and the price of materials and of all purchasable commodities have been increasing, in many cases, by leaps and bounds And it by no means follows that because a corporation's activities involve the turning over of hundreds of millions of dollars a year, that therefore it has not in considerable measure felt the pressure of these changed conditions

We have before us some statistics regarding the New York, New Haven, and Hartford Railway, which have been sent to us by its new president, Howard Elliott The pamphlet presents facts and figures regarding the situation on one of our leading railroads, of the correctness of which there can be no doubt whatsoever. Regarding the increased pay of employees, it is sufficient to say that three reports made by the New Haven Railroad to the Interstate Commerce Commission for three periods, five years apart, show that the average yearly wages based on the number of men employed have risen from $633.69 in 1903 to $763.38 in 1908 and $815.49 in 1913. In the ten years from 1903 to 1913 there has been an increase in the number of men employed of 11 per cent; an increase in the total compensation of 43 per cent; and an increase in the average yearly wage of 29 per cent. Furthermore, we are informed that during the fiscal year ending June 30th, 1914, the increase in the rates of pay will have increased the total payroll about $900,000 over the previous year.

There has been a large increase in cost of railroad operation, etc., due to legislative acts and requirements. Thus the Nine Hour law, the Ash-pan law, the Safety Appliance law, the Boiler Inspection law, and the Full Crew law, have increased the expense of the company nearly $200,000 per year. Ten years ago the cost of accounting was $190,000 per year, to-day it is about $500,000 per year, and part of this increase is due to the accounting requirements of the Interstate Commerce and State Commissions. The Federal Act calling for the valuation of railways will add another $60,000 per year to the expenses of the company. Commenting on these facts, President Elliott says that they are not quoted in any spirit of criticism, but merely to show the effect that they have had upon the income of the company.

On the question of freight and passenger rates, we learn that, although the capital investment of the company and its operating expenses have been increased, the freight rates on the whole have remained stationary or have decreased. Thus, in ten years there has been a reduction of 69/1,000 of a cent in the average rate received for hauling 2,000 pounds of freight one mile. Now this seems to be a very small sum; but when it is applied to the frieght business of the New Haven Road for the year ending June 30th, 1913, it is found that it represents a loss of freight earnings of $1,800,000. The increase in wages and the decline in freight rates, alone, make a difference of over $9,000,000 a year in income, equal to 6 per cent interest on a capital of $150,000,000.

An interesting fact in connection with the New Haven Railroad is that it is essentially a passenger railroad; for whereas on the railroads of the country as a whole two tons of freight are carried for each passenger, on the New Haven only one third of a ton is carried per passenger. During eight months of this year, the passenger earnings were 50.6 per cent, and the freight earnings 49.4 per cent of the revenue from transportation. The revenue per passenger train-mile was $1.90 and per freight train-mile $4.17. Again, the commutation and trip-ticket passengers, which are the unremunerative class of passenger travel, comprised 43 per cent of the total passengers carried, and they yielded only 13.6 per cent of the total passenger revenue. Taken as a whole, President Elliott states that, because of low passenger fares and the increasing cost of service, much of the passenger service is operated for the convenience of the public at a positive loss, and the whole passenger service only just pays its operating expenses. Hence the justice of making a reasonable increase in the passenger rates is obvious.

Reconnoitering at Santiago and at Vera Cruz

THE events of the Spanish-American war are not so far removed but most of us have a distinct recollection of the anxiety which was occasioned by the dispatch of Cervera's squadron of four armored cruisers and some torpedo-boat destroyers from Spanish to American waters. It was known that Cervera had sailed; but as to his destination there was, even in our Navy, considerable doubt and much resulting perplexity. As will always be the case in hostilities involving naval operations, our towns and cities along the seaboard became suddenly aware of the vast importance of a navy, and the timorous property holders and municipalities clamored loudly for the protection of a cruiser, battleship or something that could shoot with big guns. Meanwhile, when our scouts, improvised and otherwise, were scouring the seas in search of the Spanish admiral, he had slipped quietly into Santiago harbor, where he lay snugly screened from observation behind the rather lofty hills which encircle that anchorage.

Nor have so many years intervened since that interesting episode but most of us will recall the long-range observation of the entrance to Santiago harbor by Admiral Schley, and the many speculations indulged in by himself, the public press, and everybody else, as to whether the Spanish ships were or were not hidden inside the snug little harbor.

Vastly different are the conditions sixteen years later at the port of Vera Cruz, Mexico—different, that is to say, so far as the question of obtaining accurate information of the strength and location of the enemy is concerned. Although our enlisted men and marines had landed in considerable force and held the city, there was considerable uncertainty as to number and position of the enemy's forces outside the city. Rumor had it that heavy reinforcements had been dispatched from various points to Gen. Maas, who had been in command at Vera Cruz, and it was stated that he was making ready for an attack on the city with overwhelming numbers. Most important was it that Admiral Fletcher should be informed on this point and learn what was the condition of the railroad line from Vera Cruz to Mexico, and particularly of some important bridges on that line. It was impossible to spare sufficient officers and men for an adequate reconnaissance, and for a while the situation appeared to be somewhat critical. Then there steamed into port the "Mississippi," and [illegible] her arrival, the naval aeroplanes and [illegible] were making a searching reconnaissance of the surrounding districts about Vera Cruz and along the route of the railroad. The Mexican forces, very limited in number, were located, and the whole military situation in and about Vera Cruz was cleared up.

There is a world of significance in a comparison of the situation at these two ports in the West Indies and the Gulf; and once more the aeroplane has proved its inestimable value as a means of obtaining definite knowledge of the strength and position of the enemy.

Annual Loans for Naval Construction

WE direct attention to the letter signed "Navy" in our correspondence columns, which draws attention to startling conditions in the naval situation. The author is well known to us, and is one of our most capable naval officers, who has spent many years abroad in close touch with the naval and diplomatic situation.

The statement that some of the leading powers are supplementing their first annual naval appropriations with large annual loans, spread out over a number of years, does not surprise us. Increasingly, it is being understood that the command of the sea may mean the command of the whole situation, military as well as naval—and particularly so in the case of nations which possess an extensive littoral or an oversea trade of large proportions. The determined way in which Germany, France, and Japan are building up their fleets is not to be attributed to any mere "jingo" spirit. The motives that prompt the policy are of a lofty and patriotic character, and these large increases are the result of a broad, intelligent, and thoughtful review of the whole international situation.

The facts brought out in the letter referred to point with increasing emphasis to the need for the formation of a Council of National Defense—a representative body, with the President at its head, which, after a review of the whole naval situation the world over, shall determine upon a fixed policy of naval construction, based upon our present and probable future necessities.

Predicting Nile Floods

THE prediction of the Nile flood has been a cherished ambition of the Egyptian meteorological service for a number of years. The stages of the Nile depend upon the rainfall of Abyssinia, and this, in turn, is supposed to be supplied by moisture-bearing winds blowing across the continent from the Atlantic Ocean. Accordingly the attempted predictions are based upon observations of pressure and wind velocity at St. Helena, and pressure in South America, which indicate the activity of the atmospheric circulation over the South Atlantic. It has been found that the mean error of a prediction from these data for the mean height of the Nile at Halfa between July 16th and August 15th, which normally corresponds to the middle of the rising stage, is ± 0.33 meter, whereas a prediction that assumes that the river will be normal in any given year would have a probable error of ± 0.55 meter. According to Mr. Hurst of the Egyptian Meteorological Office, this result is sufficiently encouraging to warrant a continuation of the investigation, considering the vast importance of the problem to the welfare of Egypt.

The Cooling of the Earth

THE application of Stefan's law to the calculation of the mean temperature of the Earth, at a given latitude, shows that at the latitude of 80 degrees, the temperature was in the neighborhood of 90 deg. Cent., when the Sun's radius was about one and a half times its present dimensions, i. e., about two million years ago. Thus it would appear that life commenced on the Earth in the vicinity of the poles. The same reasoning leads us to the conclusion that in less than two million years, when the Sun's radius will be reduced by one tenth of its present value, the temperature on the Earth will have fallen below 0 degree, even at the equator.

Evaporation and Stream Flow

AN investigation of evaporation and stream flow is being carried out by Prof. John F. Hayford of Northwestern University with the aid of a grant from the Carnegie Institution. Instead of using apparatus on a small scale to measure evaporation, Prof. Hayford proposes to consider each of the Great Lakes in turn as an evaporation pan, evaluate the income, outgo (other than evaporation) and change of content of the lake, and from these data to determine the daily evaporation in its relation to meteorological conditions. Ultimately the knowledge thus acquired will be applied to a study of the laws of stream flow in the United States.

[illegible]

[illegible].—The statement that graduates of engineering schools do not follow the engineering profession is shown to be erroneous in the case of those of the College of Engineering of the University of Illinois. Data recently collected by the College show that of the 2,185 graduates, [illegible], or 89 per cent, are engaged in one way or another in engineering work, and that only 178, or about 8 per cent, have gone into other fields.

A Japanese Test Car.—A dynamometer car which has been designed for the Imperial Government Railways of Japan by Prof. E. C. Schmidt of the Railway Department of the University of Illinois, is expected to be received at Urbana this month, when the final assembling will be done. This car is being built by a prominent Chicago manufacturing company. After it has been assembled at Urbana it will be given a short preliminary run to see that everything is working perfectly, and will then be taken apart and shipped to Japan.

Preparing for the San Francisco Exposition.—By way of preparation for the heavy travel which is expected in connection with the Panama Exposition at San Francisco, the Union Pacific Railroad Company has recently placed an order for 54 locomotives costing about $1,000,000. Twenty-five of these are of the Pacific type, 15 are Mikados and 14 are of the six-connected type. Forty of the locomotives will go to the Union Pacific, 10 to the Oregon Short Line and 4 to the Oregon-Washington line.

The New German Torpedo.—The latest dreadnought cruisers and destroyers of the German navy, including all built since and during 1909, are armed with the new 21.6 torpedo, which is about 17 feet long and carries a bursting charge of no less than 290 pounds. The range is 7,500 yards, and the explosive in the head is known as trinitrotoluene, which is far more powerful than the guncotton used in the old 18-inch torpedo. In fact, the Germans believe that a single hit from the new torpedo would disable even the largest of the present dreadnoughts.

Herald Square Subway Station.—Construction of the new express station of the Broadway line at Herald Square will constitute this one of the most important traffic centers in this city. When the station and the extension of the Hudson tubes to the Grand Central Station have been completed there will be no less than six separate transit lines at this point, including three surface car lines, the Sixth Avenue Elevated, the Broadway line and the Hudson tubes, the whole being carried at four different levels. This station will reach from 32nd Street to 35th Street, and will be provided with eleven separate entrances.

Steam Turbine Pumps.—In Germany the first water works to recognise the many advantages of the steam turbine pump, as embodied in the new Allgemeine machines, was the one situated at Beelitzhof Works. Compared with the piston machines already in use there, it was seen to be much better, and this led the company to put in a new group having an output of 1,200 cubic feet a minute with a lift of 200 to 350 feet. This group is of improved type, with a steam turbine coupled on the same base to a rotary pump. All the water elevated by the pump is made to pass through the condenser (placed in the basement), so that an excellent cooling effect is the result, and the quantity of water is so large that it does not heat up to any extent.

Mississippi River Bridge to be Built at New Orleans.—It seems that the project of a bridge over the Mississippi near New Orleans, first proposed in 1888, is to be put through. The original design was for a crossing about four or five miles above New Orleans, where no change of bed or banks has occurred in the recorded history of the river. The span of the cantilever bridge was to be 1,070 feet between centers of main piers, the suspended span being 440 feet long and the anchor arms each 660 feet 8 inches in length. The foundations were to extend to 170 feet below low water and were to rest upon a bed of firm sand. The piers were to be sunk by dredging through open wells or cylinders. The present plan calls for a double deck bridge, one deck for highway and electric railway travel, and the other for railway service.

A New Road-Mending Machine.—An experimental test has been made in Paris of a portable road-mending machine, consisting of a six horse-power gasoline engine, actuating an air compressor, the air being led from a storage tank to a pneumatic rammer and a pneumatic pick, the latter being described as merely a modification of the well-known pneumatic riveter. The workman holds the tool close to the road and pushes the pick under the surface, raising it up as he proceeds. It is said that the work was done at a much faster rate than was possible with the ordinary pick. The pneumatic rammer also gave good results. One advantage of the system is that several men can work from the same compressor plant. The trial seems to indicate that mechanical road-mending is more effective than the present method.

Automobile

Catering to Convenience.—The manufacturer of a British car has provided an exceptionally simple means for cleaning the fuel tanks on his cars. He has merely made the filler cap large enough to admit a man's hand and arm. Incidentally, the large filling orifice facilitates replenishing the supply and as it makes possible heavy, substantial threads on the cap it eliminates the chance of their failure.

Protecting the Chauffeur from Head-Lights.—In patent 1,089,539 Theodore P. Driver of Melrose, Mass., shows a pair of chauffeur's spectacles in which are provided a row of three or more vertically arranged non-contiguous slats or screens. These are so arranged that the space between them is such as to afford no material obstruction to the straight ahead view, although they will operate to cut off the rays from approaching head-lights.

A Timing and Indicating Device for Vehicles.—John F. Burns of San Francisco and his assignees, Robert Colman and F. M. Auliffe, both of the same place, show in patent No. 1,090,382 an apparatus for indicating the letting of vehicles, which apparatus has a suitable timing and indicating device actuated by the seating of a passenger, the door of the vehicle controlling means for interrupting a movement of the timing and indicating device.

Germany's Municipal Motors.—A careful circular campaign has revealed that of 58 German cities having populations of more than 80,000, only 5 are without municipal motor wagons; one of these has a vehicle on order. The number of vehicles in each city varies from 1 to 52 per capita, the total number being 590. Of these, the fire brigades have 249; street cleaning and watering, 113; and ambulances, 54; the remainder are used for miscellaneous service.

A Two-Cycle Engine Competition.—By way of stimulating interest in the two-stroke automobile motor, the Royal Automobile Club of Great Britain, which already has done much to advance automobile science, has decided to organise a competition for motors of that kind. So far, nothing regarding the test has been permitted to become public, except that the test will require the engines to be fitted to a chassis and submitted to the Technical Committee of the club for certified trials. Further details probably will be forthcoming in the near future.

Agricultural Motor Trials for Africa.—There will be held in Tunis, Africa, from April 15th to 22nd, a series of tests of agricultural motor apparatus which have been organized by the General Direction of Agriculture and Commerce of the Tunis Government. Under the head "Concours de Motoroulture," they will comprise tests of all kinds of motors, wagons, tractors and general agricultural vehicles. Prizes to the amount of $6,000 are offered for best performances. The tests are conducted by the Direction Generale de l'Agriculture, 76 Boulebard Bab Benat, Tunis, North Africa.

Promise for Four-Wheel Drive Tractors.—As a result of the tests of four-wheel drive tractors, which have just been completed by French army authorities, it is likely that the number of these vehicles in use in the army will be increased. Thirteen vehicles were tested and all of them proved remarkably efficient; there were no mechanical troubles. The rules of the competition required that four-cylinder motors be used and that carbureters operate equally well with gasoline, alcohol or benzole. Some of the vehicles showed as high as 40 ton-miles to the gallon of fuel. The average consumption of the heavy tractors was 1.3 to 2.2 miles per gallon of fuel; of the light ones, 3 miles to the gallon. The supreme test required that the tractors ascend a 22 per cent grade carrying their rated capacities; no trailers were hauled in this test. All of the vehicles ascended without trouble, though but one was able to remain stationary on the hill with only one set of brakes applied.

Remarkable Strength of Steel Wheel.—In a recent test of wire, wood and steel wheels conducted by the University of Michigan, the steel wheel came out with flying colors. It successfully withstood a lateral pressure of no less than 8,940 pounds to the square inch. The tests were made in a Riehl machine. The load increments, applied at the wheel rim, horizontally, were 500 pounds and the deflections shown were as follows:

DEFLECTION IN INCHES.

Load Pounds on Rim.	Steel Wheel.	Wire Wheel.	Wood Wheel.
500	0.001	0.001	0.013
1,000	0.041	0.030	0.033
1,500	0.055	0.120	0.075
2,000	0.068	0.215	0.121
3,000	0.099	0.425	0.210
4,000	0.110	0.533	0.312
5,000	0.143	.....	.....
6,000	0.233	.....	.....

The wood wheel failed at 4,500 pounds; two spokes in the wire wheel broke at 4,000 pounds, though no nipples pulled through the rim.

Astronomy

The New Comet Recently Discovered by Kritzinger in Germany has been observed by Dr. William R. Brooks, professor of astronomy at Hobart College, Geneva, N. Y., from the Smith Observatory. Its position on April 23rd was right ascension 17 hours 41 minutes; declination north 9 degrees 41 minutes, near the head of Serpentarius, with a daily motion of about one degree in a northeasterly direction. The comet is quite faint telescopic, a broad diffused nebulosity with slight central condensation and no tail. It is growing brighter, arriving at perihelion, or nearest to the sun, the last of May.

The Total Light of the Stars.—Dr. Chapman read a paper before the Royal Astronomical Society describing investigations made on the total light of the stars. The results show that the total light from the stars is about equal to that which would be given by 630 stars of the first magnitude. The light given by stars of each magnitude increased from the first magnitude down to the tenth, the decrease in brightness of the individual stars of the successive magnitudes being more than compensated for by the increase in the number of stars belonging to that magnitude. But below the tenth magnitude this is no longer the case, the light falling off more and more as we descend the scale.

A Meteorite from Zululand.—Prof. Stanley describes the fall of a meteorite in the N'Kandhla district of Zululand, which took place on August 1st, 1912. An explosion took place, which was audible over a considerable area, and a rapidly moving body was seen accompanied by a spiral trail of smoke and emitting a rumbling or crackling sound. The meteorite discovered by Prof. Stanley fell within a few yards of a native woman. It weighs nearly 38 pounds, and consists almost entirely of nickel-iron alloy, and is therefore classed as a siderite; it is coated with a skin of magnetic oxide exhibiting flow lines and shows numerous "thumb marks." An analytical investigation shows the presence of iron, nickel, silicon, sulphur, carbon, phosphorus, aluminium, magnesium, platinum and chlorine, the bulk of the meteorite being composed of iron.

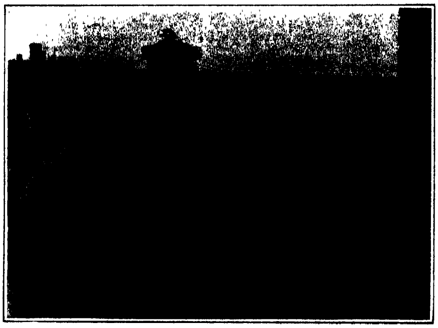
The Stability of the Solar System.—A law connecting the distances of the planets of the solar system from the sun has been discovered by Beldt, which is in close agreement with the observed facts. The mere existence of such a law throws light upon the stability of the solar system. A century ago Lagrange and Laplace thought they had demonstrated the invariability of the mean distances of the planets, and from that the stability of the solar system. But the mathematical series used in this investigation have been shown by Poincaré to be divergent, and therefore, so far as those calculations go, the stability is uncertain. If, however, the distances of the planets had been changed since the origin of the world by the action of the tides, their mutual attraction, etc., and if the perturbations so caused had accumulated, they would have been different for different planets, and no law connecting the distances of the planets and their satellites would have been discoverable.

Astronomical Telegrams.—The last annual report of the Director of Harvard College Observatory reviews briefly the telegraphic arrangements by which announcements of important astronomical discoveries and observations are given to the world. The distributing center in America is the Harvard Observatory; in Europe, the Kiel Observatory. A new object discovered in one continent is likely to be observed in the other on the following evening; hence the necessity for this prompt interchange of information. The expense of cabling American observations to Kiel is borne entirely by the Harvard Observatory. Cablegrams received from Kiel are generally distributed in this country by "night letter," and may thus be transmitted in ordinary language instead of cipher without increasing the expense. They are sent to all institutions and individuals who express a wish to receive them and who are to pay the telegraph charges from Harvard. During the year ended September 30th last, 33 telegraphic announcements were made, mainly relating to the discovery of comets.

The Shape of the Earth.—On the earth and on Mars the oceans dominate the austral hemisphere. This fact may be attributed to the translation of these two planets in a south-north direction across the primitive nebula. The rotation so set up would result in the production of cold currents which might cause the temperature to become inferior to 364 degrees, the critical temperature of water, and the currents would be such as to cause the condensation of the oceans to be produced round the South Pole, and to determine that the direction of the currents should be toward the equator, which explains the pointed form of the austral continents. The theoretical calculation of the velocities of these currents and the amount of solid matter transported by them is verified by direct measurement. Thus, 2,000 meters beneath the surface of the sea, the magnitude of the oceans is constant on the parallels of the austral hemisphere, and the magnitude of the continents is constant on the parallels of the boreal hemisphere.

Hydraulic Train Stops

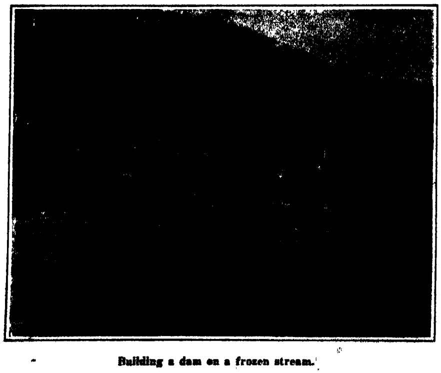
THE sudden stopping of trains at terminal stations has long been a source of continual annoyance to travelers, and in many cases has been the cause of serious accidents. A train stop, or what is technically known as a "buffer," that will reduce the speed and concussion of the incoming train to a small fraction of resistance, has long been needed on most of our railways. A hydraulic buffer of very interesting design has been developed by a firm of English engineers. It will resist and stop trains without the slightest recoil, that may be running at speeds of from 6 to 10 miles per hour. It consists of one, or a pair, of cast-iron cylinders mounted upon a concrete foundation, and the front castings project forward, carrying the piston rod or rods. Each rod is fitted at its outer end with a buffer head. The cylinder is entirely filled with water, and passages are provided so as to permit the water to flow from behind the piston to the front as the piston makes the home stroke. These openings are very much larger at the front than at the back. As the speed of the train is diminished, and the recoil of the piston takes place, a lesser area is provided for the water. For this reason an almost constant resistance is provided, and the incoming train is stopped without the sudden shock usually experienced. A relief valve is provided in the front casting which takes care of the equivalent amount of water displaced by the piston. The resetting of the piston is done automatically by means of a constant supply of water which is brought to the front part of the cylinder at a pressure of about 35 pounds to the square inch. This acts upon the area of the piston rod and immediately forces it into position again ready for the next train The illustration shows an 8-foot oil buffer. This is operated entirely by oil, which is forced, after having accomplished the action of the piston in checking the train, into the receptacle shown on the front of the forward casting, and may be used over and over again. In this case the return stroke of the piston is made through the use of compressed air which is available on the line.



Oil buffer to stop trains without shock.

Building Dams on the Ice

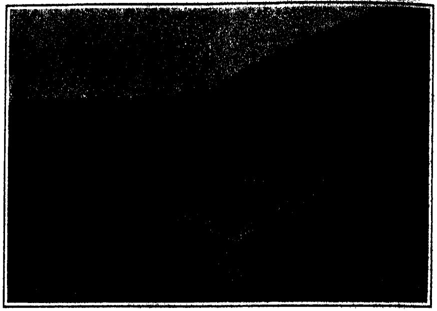
THE Government engineers on the Upper Mississippi have found that by constructing the dams on the ice in the winter they can often build them in shallow places and across sand bars which are inaccessible to the barges and steamers in the summer months. The work also can be done much more cheaply. The willows and rock are hauled upon the ice by teams and unloaded at the place where the dam is to be constructed. The building crews follow the same method as is used in the summer months. A mattress of willows is made, loaded with rock, a second willow mat laid on top and so on until a dam of the proper height is constructed. When it is finished, the ice is cut away and the structure sinks to the river bed of its own weight The work on the ice has been progressing for three years all along the upper half of the river. Less has been accomplished this year than usual because of the thinness of the ice.



Building a dam on a frozen stream.

Primitive Bridge Engineering in Peru

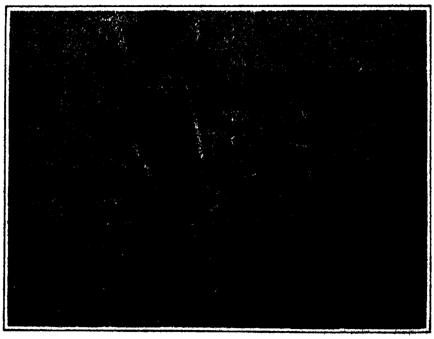
THE curious suspension bridge shown in the accompanying [illegible] was built by the native Indians of Peru. It may be found across the mountains from Lima, in the Huancayo Valley, near Jauja, spanning the [illegible] River. Being a mountain stream, subject to sudden torrential floods, substantial towers have been built at each side, which provide secure anchorage for the cables and raise the floor of the bridge well above high water. The floor is hung from the cables by means of diagonal, as well as vertical lines, so as to prevent the bridge from swaying lengthwise. Side sway is prevented by guy lines running from the center of the bridge to each side of the towers. The water under the bridge is on its way to the Atlantic Ocean, *via* the Amazon River. A journey of over 3,000 miles lies before it.



Curious suspension bridge built by Peruvian Indians.

Obtaining Potable Water from the Muddy Colorado

AT the conception of the wonderful plan to divert the waters of the great Colorado River for the purpose of reclaiming the arid Colorado desert in California, no consideration was given the quality of the river's water. All that then concerned the adventurous engineers was to wet the thirsty land. Now that this has been accomplished and the famous Imperial Valley has blossomed into a land of immense agricultural activity, and half a dozen thriving towns have cropped up with an aggregate population of over 40,000, the problem of wetting the palates of these people has become a far more delicate undertaking than that of merely wetting the land. On its long winding course through the Grand Canyon country of Arizona the Colorado becomes supersaturated with a very fine silt, and this it carries on down into California and through the great Imperial Valley irrigation system, which covers an area of 350,000 acres. All the water used for drinking in the valley, both on the ranches and in the towns, has to be taken from the thick, chocolate fluid which runs through the big irrigating ditches.



Silt precipitated out of the drinking water of Brawley, California.

When the water arrives at Brawley in the extreme northern end of the valley, it has a molasses consistency and an invincible flavor. The 3,000 inhabitants of the town of Brawley consume 200,000 gallons of this water daily. In order to prepare the ditch water for drinking, the town has a municipal water plant. There are several large reservoirs or settling basins where the mud in the water is at first allowed to precipitate, the clear water afterward being pumped into an elevated storage tank from which it gravitates through the city mains.

The settling basins were made by inclosing an area of ground 200 feet square with battered earth walls to a height of 12 feet. The full head of the ditch water is run directly into this until the water is 6 or 7 feet deep, after which the supply is cut down to the actual amount consumed by the people daily. At the end of the settling basin, farthest from where the ditch water is received, a small raft is anchored. This supports an open-end, vertical pipe which is submerged about 6 inches below the surface of the water. This pipe is connected with a main from the pump house, and conveys only the surface water of the settling basin which is usually very clear.

The accompanying photograph illustrates what a great amount of mud is precipitated in these basins. The view shows the bottom of one of them after the water was drained off. The man is standing on the original floor of the basin. The 30-inch deposit was precipitated during a period of twelve months.

X-Ray Moving Pictures of the Digestive Tract

A New Way of Studying Diseases of the Stomach

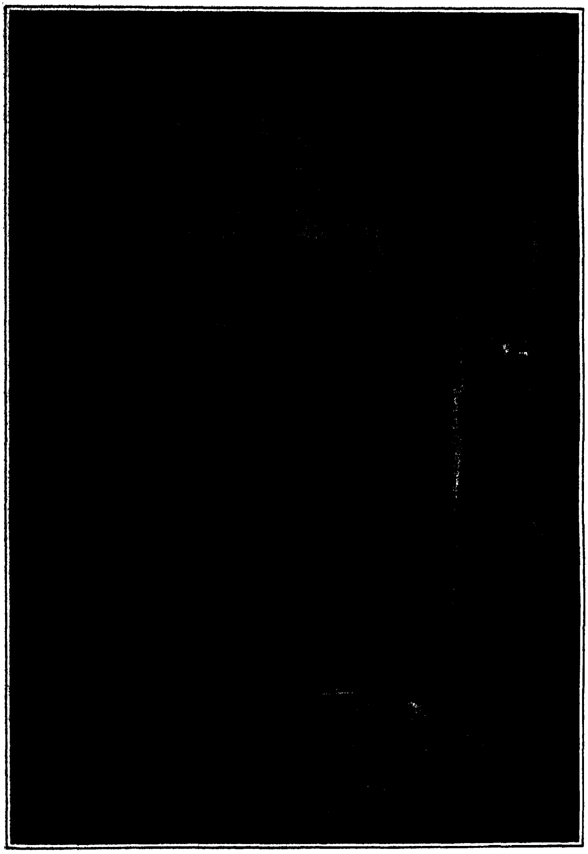
By Herbert T. Wade

AMONG the recent advances of medical science none has been more marked and conspicuous than progress in treating the various diseases of the digestive tract, particularly those of the stomach and the intestines. This has been made possible in great measure by modern methods of diagnosis in which quantitative and positive results have been secured in various ways, one and not the least of which has been the study of the digestive tract by means of the Roentgen rays. With the development of improved Roentgen ray tubes and a better understanding of methods for their use and application, it was realized that by filling the stomach or digestive tract with material opaque to these rays and making a radiograph or shadow picture of such a fluid cast in relation to the adjoining organs, the progress of digestion could be studied. This accordingly was done, and to-day in diseases of the stomach and intestines it is quite usual to secure a radiograph or plate on which is recorded such a fluid cast of the stomach and intestines filled with the opaque substance, and then make a Roentgenographic diagnosis.

This opacity is obtained by a mixture of bismuth or barium and buttermilk administered to the patient under examination, and the progress of this material, as it passes from the œsophagus into the stomach and is acted upon by the stomach and then passes out into the intestines, can be studied. Hitherto it has been feasible to take such a radiograph only at various stages of the process, although since the development of motion pictures and motion picture apparatus the desirability of Roentgenokinematographs, or X-ray moving pictures of the stomach, made to demonstrate and record not only the condition, but its actual movements or gastric motor phenomena, has been appreciated and attempts at its realisation made. As early as 1909 a series of successive Roentgenograms of the stomach were made by Doctors Kaestle, Rieder, and Rosenthal. Inasmuch as only thirteen of these pictures were made in 22 seconds, it was apparent that while a beginning had been made, with such slow speed true kinematography hardly could be attained, and the results were little more than an improvement on an ordinary series of Roentgenograms.

Recently, as the result of working on apparatus to make serial radiographs of the stomach and intestines, a special apparatus has been devised by a distinguished Roentgenologist, with which it is now possible to secure true moving pictures on an ordinary sensitized film at various stages of the digestive process at the rate of at least four exposures a second. Thus the churning effect in the stomach and the peristaltic or muscular action in the intestines by which the contents of the alimentary tract are advanced, after being duly acted upon, can be studied by means of motion pictures, which, when reproduced, graphically show by the movement of the silhouetted image the action that is taking place.

This new method has been made possible in large part by the new Coolidge Roentgen ray tube described in the SCIENTIFIC AMERICAN of February 21st, 1914, which secures in its operation greater stability and evenness of penetration as well as susceptibility to more accurate regulation, thus giving more even radiographs.



Apparatus for taking moving pictures of the stomach.

The apparatus *for* making the moving pictures consists of the usual lead-lined table in a dark booth with the Roentgen ray tube above in the usual position and the customary rotary transformer, or other devices, for its exciting, along with the special mechanism for securing the movement of the film and the periodic exposures. The patient is placed on the table, face downward, with the Roentgen ray tube directly above the stomach. There is a square opening in the table beneath, across which, through suitable guides, the film passes, being wound from one spool to another, as in an ordinary film camera. This film is eight inches in width and is supplied on spools which, as at present constructed, are capable of 25 or 50 exposures. Directly beneath the film is located an intensifying screen coated on its upper side with calcium tungstate, a fluorescent material that glows brilliantly when excited by the Roentgen rays striking its surface. Naturally, when the rays from the tube in their passage through the body encounter any body or substance opaque to them, as a bone, there will be a corresponding shadow on the fluorescent screen, and the variation in intensity of the shadows of different organs, or material, of course is the basis of the whole operation The actual effect of the intensifying screen is to emit actinic light under the influence of the Roentgen rays from the tube above The film itself is not acted upon directly by the Roentgen rays, but by the rays which are sent out from the fluorescent screen A second fluorescent screen, with its lower surface coated, located directly beneath the first, may be observed by the operator either directly or by means of an inclined mirror. In this way the position of the patient can be arranged so that the stomach can be centered on the film, and, at the same time, the action of the apparatus observed. The operator or the diagnostician can observe the process fluoroscopically and need not start the film in motion until the desired stage is reached.

The film has at its edges regular perforations to engage studs correspondingly placed on the circumference of sectors connected with the driving mechanism so that it may be moved regularly, but intermittently, across the opening where the shadow falls The apparatus is arranged so that six exposures a second may be made, and the exposure takes place automatically when a fresh section of the film is placed at the opening The mechanism operates by means of shafts and appropriate gearing, and there is arranged in connection an electric switch that works automatically in conjunction with the advance of the film, closing the circuit of the transformer supplying *the alternating* current, and lighting up the tube instantaneously as each fresh surface of the film is brought in position. Accordingly, there is a regular series of exposures of the shadows produced on fresh surfaces of the film and the phenomena occurring in the stomach and intestines can be observed and recorded. In this way, when the film is developed a series of pictures is obtained where the various exposures can be studied both individually and collectively in connection with one another, or they may be reduced by ordinary photographic methods for reproduction in the usual motion picture projection apparatus. The time of the passage of the film can be controlled by the operator and other adjustments made so that the exposures following each other in regular succession make possible a study of the peristaltic action, which is a regular and involuntary muscular contraction of the stomach, or intestines, with a period of from 15 to 20 seconds in the case of the stomach. Not only do these motion pictures enable some definite idea to be formed of the peristaltic action taking place in the stomach, but they promise in the future to put at the disposal of the diagnostician, or investigator, additional information regarding peristalis in the pylorus, or lower opening of the stomach, as well as in the upper part of the small intestine, or duodenum. Some twenty-five exposures can be made of a single antrum, and sharp and interesting pictures can be obtained.

The mechanical arrangement is indicated in the accompanying illustration, which shows the apparatus as arranged in a modern Roentgen ray laboratory. The operation is practically automatic. Once the patient is in position and the instrument adjusted, a fluoroscopic observation first is made visually, and the film can be rapidly unreeled and the exposures made. After development the diagnostician has a record of the condition of the gastro-duodenal tract, or the film may be reproduced reduced in size and made available in an ordinary motion picture projection apparatus, so that the record may be thrown upon a screen and the actual motion studied, synchronized to the original time of occurrence. Moving pictures have been applied to a greater or less extent in the study of disease and diagnosis, but this is believed to be the first satisfactory attempt at using them in connection with the Roentgen rays and with a special and efficient form of apparatus.

A Huge Dipper Dredge for the Panama Canal

UPON the cover of the present issue we show the huge dipper of one of the two large hydraulic dredges which have recently been completed for the Panama Canal The dipper can take up at a single scoop, 15 cubic yards, or say about 20 tons of material, and its huge proportions can be realized from the fact that it has held a group of thirty-four men, standing upon a platform built for the purpose when the photograph was taken.

The two dredges, which are known as "Gamboa" and "Paraiso," have been built at the yards of the Staten Island Shipbuilding Company. Each dredge displaces about 1,500 tons, and each, in addition to its 15-cubic yard bucket, has one other of 10 yards' capacity. It is expected that when in regular service the two dredges together can take out about 600,000 cubic yards of material per month.

The 15-cubic yard dippers have been built with massive manganese steel lips and dipper-door hinges of forged steel which are 6 by 10 inches in cross section. The dippers are 10 feet 9¼ inches in height from the bottom band to the upper edge of the lip. They are hung on a 3¼-inch, single-part, wire rope, hoisting cable. The dredges can dig to a depth of 50 feet below the surface of the water.

The dipper handle is 72 feet long, with top and bottom bars measuring 2 inches by 12 inches in cross section The weight of the dipper handle is 81,000 pounds.

The dipper boom is 62 feet long, weighs 113,000 pounds, and is of plate-girder construction. The pins for the sheaves on the boom are 11 inches in diameter, and the parts are larger than any built before for this purpose.

The main hoisting machinery consists of horizontal, twin-tandem, compound, condensing engines, with cylinders 16 and 28 inches in diameter by 24-inch stroke. The engines are compound geared to heavy spur gears about 12 feet in diameter. These gears are mounted on each end of a 16-inch main hoisting shaft which carries the cast steel drum.

There is an independent 12- by 16-inch engine of the link-reverse type for operating the swinging machine.

The spuds at the forward end of the dredge are of unusual size, being 4 feet square and 72 feet long. They are built with cast-steel diaphragms, 5 feet apart, and continuous 10-inch I-beams in the middle of each side plate for its full length. The maximum reaction on the spuds when the digging takes place over the side of the dredge is about 700,000 pounds The spuds are placed sufficiently far back from the front of the dredge to make possible a swing of 180 degrees.

The Current Supplement

THIS week's SUPPLEMENT brings the concluding instalment of P W. Bridgman's report on his researches on the properties of water and ice at high pressures—A working model for demonstrating the effects of vegetation as a check to erosion is illustrated and its construction is described.—W. P Dreaper writes of the research chemist in his relation to the textile industry. —A discussion on the sintering of iron ore, which took place at a recent meeting of the Engineers Society of Western Pennsylvania, is reported.—The erosion of canal bottoms by the action of boat propellers has caused much trouble. Prof. O. Flamm has devised means of preventing this, which are described—F. C. Perkins writes on electrically operated tools.- The third of Sir J. J. Thomson's lectures on Recent Discoveries in Physical Science appears in this issue.—H Guenther describes the Electro-cardiograph and Its Use—C. H. Townsend tells us how a school of five live porpoises was brought from Cape Hatteras to the New York Aquarium.—F. R. Moulton gives a popular exposition of the solution recently found by Karl F. Sundman for the classical problem of three bodies.

An Innovation in Ship Salvage

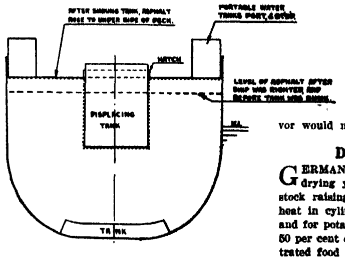
By Robert G. Skerrett

THE salvage of a steamer in grave peril because of a shifted cargo was accomplished a short while ago in a decidedly unique manner. The performance incidentally shows us the naval architect from an unusual angle and, incidentally, illustrates the advantage of technical training when applied elastically.

The craft in danger was a Danish freighter, the steamship "Berlin," bound from Trinidad, with a cargo of nearly 8,000 tons of crude asphalt, and on her way to New York city. The asphalt was from a new lake, and seemed even at the time of shipping to be somewhat more plastic than the usual run of that substance. It was stowed in the ship's regular cargo space, and aft the hold was divided longitudinally by a center-line bulkhead. However, there was no reason to expect trouble, and all went well until the vessel was some distance on her journey; but then the mischief began in earnest.

Suddenly from the northeast the "Berlin" encountered a heavy gale, and for days the wind blew fiercely, and the seas rose higher and higher as she nosed her way along through the Gulf Stream. She had to slacken speed, but with a sound hull and well-secured hatches there was no apparent cause for alarm. However, the warm waters of the Gulf Stream had been working unnoticed upon the cargo of asphalt, slowly heating it through and making it fluid. Somewhere north of Bermuda the "Berlin" was hit by three exceptionally heavy seas, one after the other, and without any warning the craft quickly heeled over to an angle of 21 degrees and staid there! The surging asphalt had broken the center-line bulkhead away from its fastenings top and bottom at the after end, and this had allowed the cargo to shift

The vessel seemed in imminent peril of turning turtle, and something had to be done, and done quickly. The engineer's force began the toilsome work of removing the coal from the listed bunkers, while the deck crew and the navigational officers went at the desperate task of trying to secure the upper edge of the ruptured bulkhead. By almost superhuman efforts, lasting well nigh for twenty-four hours, this was effected, but nothing could be done to catch and hold the lower end of the partition. After a fashion, the ship was righted somewhat, but there was still a menace in that loose bottom of the bulkhead.



AFTER SINKING TANK, ASPHALT ROSE TO UNDER SIDE OF DECK.

DISPLACING TANK
W.L.
TANK

SECT AT AFT. HOLD

As the ship rolled toward the side where the bulkhead plating should have been fastened, the partition gave somewhat like a pump leather and allowed the asphalt to surge through the opening toward the listed side. Again, when the ship rolled oppositely, the plating closed the breach and kept the asphalt from flowing back again. Thus, the motions of the vessel and the flexing of the bulkhead acted just like a pump, and raised the level of the threatening fluid four feet higher on one side than on the other. Fortunately, the deck and the hatches held, although the ship had a serious list, and, after an exhausting struggle, the "Berlin" made harbor at Cape Lookout, North Carolina. Her further relief had then to come from regular salvors.

A New York salvage concern that has done some rather remarkable work was asked to bid upon the job of sending a relief vessel to take off a thousand tons of the "Berlin's" cargo, and, together with the Danish craft, to bring both vessels to New York. The asphalt was then far from fluid enough to be pumped out, and to remove by digging would have been a long and a very toilsome, not to say expensive, undertaking. The salvors wanted an easier solution of the pending problem, and just at this stage Mr. R. H. M. Robinson, lately a naval constructor in the United States Navy, was called into consultation. It did not take Mr. Robinson long to figure out that two wooden tanks, one on each side of the upper deck, 5 feet wide and 100 feet long, would hold double the amount of water ballast necessary to trim the ship to an even keel against the listing moment of the [illegible] [illegible]. [illegible] [illegible] surging, each tank was subdivided [illegible] [illegible] compartments, and 131 tons of water were [illegible] [illegible] [illegible] the craft when this ballast was put in the [illegible] [illegible] the [illegible] side. The idle tank was held in reserve [illegible] [illegible] any emergency should the asphaltum shift to the opposite side en route to New York.

But this was not the entire solution of the difficulty, and to Mr. C. F. M. Jack, another naval architect of New York, credit is due for the clever [illegible] by which the cargo was made to fill the entire hold up to the under side of the deck, and was thus held in place so that it would have no chance to shift again. In one of the big hatches a tank was fitted and loaded until, in sinking, it displaced the asphalt. A crude stuffing box was made out of the cargo hatch coaming, and the displacing tank thus became a weighted hydraulic plunger free to move up and down and to absorb strains that would otherwise have been transmitted to the covering deck.

According to the previous estimates, and counting upon removing a thousand tons of the cargo, it was clear that many days would have been required to get the ship on an even keel again and ready to resume her run northward. But even so, with that work done, there would have been no certainty that the remaining cargo might not have caused more trouble. By the adopted method it took just three days to build the tanks of wood and to fit them in readiness for service The tanks were made of heavy planking lined with tarred paper, and the displacing tank was loaded with bags of sand, sand being a readily obtained material of nature's providing down on the Carolina coast. From the time the salvors started southward from New York until the "Berlin" reached the metropolis under her own steam was a matter of just eleven days.

But for the naval architect's few minutes of figuring, by which he determined how much deck weight moved laterally would be needed to effect the change of trim desired, many days would have been lost in following the usual procedure in digging out that difficult cargo. Time was saved, money was saved, and a unique remedy was evolved, which may have many practical advantages in meeting kindred conditions in the future. The ordinary salvor would not have thought of this expedient.

Dried Yeast as a Cattle Food

GERMAN breweries are going into the question of drying yeast with a view to producing food for stock raising. Such yeast is dried at a rather high heat in cylinders, such as are used for milk powder and for potato drying. The dried yeast contains about 50 per cent of albuminoid matters and forms a concentrated food which can be used to good advantage for most stock when mixed with other foods, and is relished by cows, sheep and horses. With cows, the percentage of butter in the milk is increased, and for horses it is said that half the grain is economically replaced by mixed dried potatoes and dry yeast. Within three years the number of yeast-drying plants increased from 5 to 26, counting 11 in Germany. It is now introduced for human food, but in this case the yeast is freed as much as possible from the bitter principle due to the hop. Such prepared food is said to be easily digested and assimilated, and Völtz and Baudrexel showed that its value is three times its weight of moderately fat meat. It not only serves for food, but acts very favorably on nutrition owing to the lecithin contained in the proportion of about 2 per cent. According to Hayduck the product, even though it costs $0.60 per pound, costs less than meat for equal food value. It is probable that the price will be lowered when it is produced on a large scale, and no doubt it will be frequently employed in the food industries as a very economical source of albuminoid substances.

Uncorking a Bottle

IT often happens that in attempting to uncork a bottle, the stopper is forced into the bottle instead, and it thus floats on the liquid. This would perhaps not be a drawback were it not that each time the bottle is to be emptied the cork comes to the neck and causes an obstruction, preventing the flow of the liquid. This can be avoided very readily, and all that is needed is to bend a piece of stiff iron wire in a long U-shape, properly fitting it in the neck of the bottle so that the loop portion projects somewhat below the neck. Upon overturning the bottle, the wire loop prevents the cork from reaching the neck to obstruct it.

Gamma Rays Produced by Roentgen Tube

ACCORDING to a special cable dispatch to the SCIENTIFIC AMERICAN, Director Dessauer of the Veifa X-ray Tube Works, Frankfurt a. M., has succeeded in producing highly penetrating rays similar to the gamma rays of radium, by means of [illegible] Roentgen tubes.

The Urgent Need for an Increase of Our Navy

To the Editor of the SCIENTIFIC AMERICAN:

In the admirable series of articles which you are publishing in the SCIENTIFIC AMERICAN on the "Problems of the Navy" you published two tables, one of personnel of the three leading navies, and the other naval tonnage, built and building, 1912. I would request that you publish the following tables brought up to January 1st, 1914, for the five leading naval powers. The joker in the naval tonnage, built and building, is the large loans which France, Japan, and Germany are making for new construction, and which do not appear in the ordinary naval estimates, thereby lulling us to sleep under a false apprehension. These tables are not attractive, but they will bear careful study by any one who is really interested, and are very illuminating. The one thing we all fail to grasp is that the pre-dreadnought battleships and armored cruisers must soon be passed out and their place taken by dreadnoughts. The proposition to convert the only five scout cruisers we have, viz., the "Chester," "Salem," "Birmingham," "Minneapolis," and "Columbia" into fast merchant vessels for commercial purposes is fantastic, unless we recognise the necessity for building up-to-date scout cruisers with 4 inches of side armor and 28 knots speed, similar to those now building abroad. We are woefully lacking in torpedo boat destroyers, but the type we are now turning out, if made a little smaller and cheaper, would be ideal. The only reason the tonnage has been increased is that in the absence of scout cruisers, of which we have practically none, no one needs to be a prophet to see that torpedo boat destroyers will, in case of war, be used as scouts, for which they were not intended, and we will be without destroyers for the protection of the fleet.

The tables are as follows:

TABLE I.

NAVAL TONNAGE BUILT AND BUILDING JANUARY 1, 1914.

Item.	Great Britain.	Germany.	United States	France.	Japan
(1) Naval appropriation	$385,213,496	$112,037,576	$140,736,526	$122,493,753	$74,383,783
(2) Amount voted to new construction	77,862,162	53,240,546	35,825,695	63,655,515	26,278,631
(3) Percentage devoted to new construction	33%	47%	25%	44%	54%
(4) Resultant new construction in tons	538,580	284,870	161,842	230,264	204,900
(5) Total tons already built	2,062,711	943,338	760,002	645,891	497,199
(6) Total of (4) and (5) tonnage built and building	2,601,291	1,228,208	921,844	876,155	702,099
(7) Dreadnoughts and battle cruisers built	27	17	*10	2	3
(8) Dreadnoughts and battle cruisers building	15	9	4	9	7
(9) Capital ships, new (dreadnoughts)	42	26	14	11	10
(10) Pre-dreadnought battleships on hand	40	20	24	18	13
(11) Pre-dreadnought armored cruisers on hand	34	9	11	20	13
(12) Unarmored cruisers built and building	82	44	14	10	14
(13) Torpedo boat destroyers built and building	187	142	62	86	56
(14) Submarines built and building	94	36	51	93	15
(15) Coal colliers	1	2	11	1 (small)	0
(16) Coal and oil colliers, or oil only	12 (small)	0	13 (large)	1 (small)	0
(17) Supply ships	0	0	5	1 (small)	0
(18) Ammunition ships	0	0	1	0	0
(19) Repair ships	3	0	2	1	0
(20) Hospital ships	2	0	2	0	2
(21) Transports	0	0	5	1 (small)	0
(22) Mining ships	7	4	1	2	1

* This includes the "Michigan" and "South Carolina" as dreadnoughts.

TABLE II.

PERSONNEL OF NAVIES, JANUARY, 1914.

	Great Britain.	Germany.	United States	France.	Japan
(1) Total number of flag officers allowed	96	40	18	45	67
(2) Total number of captains and commanders	683	356	207	360	259
(3) Total other line and engineer officers	3,835	2,852	1,549	2,022	2,831
(4) Total warrant officers	2,693	2,696	867	2,445	1,553
(5) Total line, engineer and warrant officers	7,394	5,934	2,641	4,872	4,710
(6) Total enlisted men	115,208	60,920	49,854	60,505	43,847
(7) Ratio of enlisted men to line, engineer and warrant officers	1 to 16	1 to 10	1 to 19	1 to 12	1 to 9
(8) Marine officers	471	169	345		
(9) Enlisted men (marines)	21,083	5,507	9,921		
(10) Total medical officers	593	322	314	394	373
(11) Total pay officers	655	267	231	219	362
(12) Total naval constructors	118	159	75	175	143
(13) Total chaplains	151	28	24		
(14) Total officers and men	145,563	73,396	63,413	63,859	49,435

COMMENTS ON THE ABOVE TABLES.

Items (1), (2), and (3).

France has raised a loan of eighty-one million dollars for new construction, of which $28,002,685 has been added to the regular annual appropriation of ninety-four millions for the year 1914. Japan has also raised a loan, or provided by taxation, for $78,337,869 to be added to the regular annual appropriation for 1911 to 1917. Since 1909 the German government has raised annual loans to meet the extraordinary extension of naval expansion amounting now to about $220,000,000. Not only is the present generation not finding this money, but also the interest on the loans, and the annuities for the repayment of these loans do not appear in the naval estimates in any form. Consequently the actual expenditures of Germany are far higher than [illegible] in the estimates here given. Therefore, in the above table, Great Britain and the United States are the only governments which are not contracting loans for naval expansion. Germany has a fixed programme whereby in 1921 she is to have a fleet of 41 new dreadnought battleships, 20 armored cruisers, 40 light cruisers, 144 destroyers, and 72 submarines. The fixed charges which each country has to meet each year to merely maintain what navy they have without providing for new construction is about—Great Britain, 158 million; United States, 105 million; France, 66 million; Germany, 52 million; and Japan, 48 million. In the three last-named countries they have "conscription" and the pay is very, very small.

Items (4) to (15).

Items (4), tons of new construction, and (8), dreadnoughts building, show that the United States is on the toboggan slide to fourth or fifth place. The 25 per cent of item (3) shows this also. It is idle to fall back on items (10) and (11) of old ships which we had before the era of the all-big-gun ships. People with automobiles of the vintage of 1900 are living on the side streets. Other countries about crushed by taxation are raising taxes to catch up and get in the game. We alone are hypnotized by political oratory and self-complacent bumptiousness. Needed, immediately, a Council of National Defense, and a loan of $100,000,000 to increase the number of officers and men, build 10 battleships, 20 light cruisers for scouts, 36 torpedo boat destroyers, and 25 submarines.

Items (15) to (22).

It will surprise many people to learn that our Navy is the only one which has developed a fleet of auxiliary ships of special design for supply and service of the fleets in time of peace, ready for war. Other navies rely on chartering in time of peace, and buying and chartering in time of war the necessary merchant ships to carry coal, oil, provisions, ammunition, marines, and the sick.

Our new repair ships are superb, but we are lacking hospital ships. We have been quietly accumulating these ships, and may now stop, provided we build colliers of the same type for the service of the Panama Canal, or build other ships to run as merchant vessels in time of peace, as proposed by Senator Weeks for our now inadequate scout cruisers (we only have about five in all). The questions of any further auxiliaries, except two new hospital ships, should be taken up as a passenger and freight service in time of peace. The two hospital ships owned by Japan are regularly run between Nagasaki and Shanghai in time of peace as passenger vessels.

The mine ships of foreign navies are necessary because in all other navies than our own the coast and harbor defense is under the navy. With us it is under the Army. The one mine ship we have in the Navy is for the protection of the fleet. NAVY.

U. S. S. "Michigan," *en route* Vera Cruz, Mexico, April 21, 1914.

Mobilization and a Naval Reserve

To the Editor of the SCIENTIFIC AMERICAN:

The article, No. VIII, "Mobilization and a National Naval Reserve," in the April 18th issue of the SCIENTIFIC AMERICAN, is one of the ablest articles dealing with our great national need which has ever been published. It should be read and studied by every member of our Congress, and by every constituent.

That nation which can best guarantee its own peace and protection is the one best prepared for war. The cost of preparedness is but a fraction of the cost of war to a nation unprepared.

Do not our people realize that all the other great nations are quietly and grimly preparing for war in spite of peace conferences

Your article was patriotic, highly commendable, and unless we awake, will prove equally prophetic.

Daytona, Florida. L. M. DRAKE.

The Perils of Electricity

To the Editor of the SCIENTIFIC AMERICAN

I am sending you the following excerpt from the editorial columns of a local paper, thinking that you might be interested in hearing of the great peril in which the world is placed:

"This matter of handling electricity is getting to be a dangerous thing. At Madrid, Spain, Senor Igelsias recently 'lighted and extinguished at will fifteen electric bulbs at a distance of 600 yards.' It is also claimed that in February William Marconi lighted an electric bulb at a distance of six miles, by a wireless current. Electricity to do this must be very powerful In the hands of a villain, electricity may yet be so used as to set whole cities on fire, kill individuals at will without being liable to even the least suspicion And if individuals can be slaughtered, why not entire armies and whole communities? One cannot tell where all this will end."

After much careful consideration the only remedy which I can see is that we who have enemies who are electrically inclined refrain from carrying around with us in our pockets receiving plants strung up in series with a pound of dynamite. I realize that this would be a great sacrifice, and yet, for the sake of the world, we should do it. OSWALD C. BREWSTER.

Boulder, Colo.

Centrifugal Force Versus Screw Lift

To the Editor of the SCIENTIFIC AMERICAN:

Every little while someone brings out an invention in which a propeller is to be run in a hood or tube, although it has been well established that better results and higher efficiency can be attained by running the propellers in the open. Only last year one of our most prominent aeroplane builders was experimenting with propellers in his research laboratory, with the aid of a wind trunk; and he was quite undecided whether to run inclosed propellers or to place them in the full-sized wind passage.

Several years ago the writer was experimenting with centrifugal pumps, and while at work with his first model had an experience so unexpected, and that was so baffling as to fix it in his mind as a lesson well worth remembering. He would like to pass it along, and trusts that it may not prove unprofitable reading to you.

The pump model was exceedingly simple, being a piece of shafting about 2 inches in diameter by 15 inches long, deeply threaded with two opposed screws similar in appearance to the screws of a meat chopper. The screws were equal in length and pitch and were right and left hand. A space was cut out in the central part of the shaft, the intention being to have the screws pump toward each other, thus equalizing the end thrust. This opposed screw shaft was run in a well fitting hard brass tube that had an outlet delivery at its center and adjacent to the space in the shaft between screws.

You can imagine my surprise when I found that the submerged twin screw could be driven at a very high rate of speed; probably it was turning at from 3,000 to 4,000 revolutions per minute, and yet the water was practically at a standstill, surging slowly up and down about three quarters of an inch in height in the outlet tube.

After considerable study I reached the conclusion that the screw lift was nearly balanced by the centrifugal force, and its reflex action against the inflowing water. No doubt viscosity and adhesion played an important part, yet for want of time I was unable to experiment in that line My defeat, however, pointed the way to balanced and opposed screws or scrolls that operate in parallel planes of centrifugal action.

Later experiments would indicate that any centrifugal pump could be reversed in rotation, and running in that manner would pump a little; this proves to my mind that centrifugal force, when aided by adhesion and viscosity, is greater than screw lift at the same radius and speed. WALTER A. SIMOND.

Franklin, N. H.

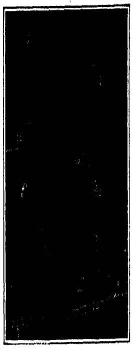
Making the Navy's New 14-inch Guns

By Louis E. Browne

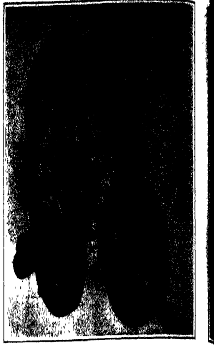
ON Sunday, April 26th, there sailed to Mexican waters the new dreadnought "New York," which was recently completed at the New York navy yard. She will be followed in a few days by the sister ship "Texas." The delivery of these ships to the Government will mark an epoch in naval construction, for they will be the first ships to mount 14-inch guns These ships will be by far the most heavily armed in the world The ten 14-inch rifles are arranged in pairs in five turrets, all of which are upon the ships' center lines This design, adopted by the Navy several years ago, enables every gun in the main battery to fire on either broadside

Experiments with the 14-inch rifle began in 1900, and it was adopted by the United States Navy as its standard big gun late in 1906 Like the 12-inch rifle, the new guns for the dreadnoughts now building are of the built-up type, consisting of the tube, or lining, jacket and several hoops No single casting could withstand the enormous stresses resulting from a modern firing charge The guns are built in parts and shrunk together to give vastly greater strength

The Navy requires steel of the highest grade of perfection for the new guns An increase in the principal properties of malleability, ductility, hardness, toughness, tensile strength, and elasticity was desired While not greatly superior to the steel used in the 12-inch guns, the metal which goes into the new 14-inch rifles is slightly superior A steel containing something more than three and one fifth per cent of nickel was selected. The Bureau of Ordnance requires that all steel gun castings be made by the Whitworth and open hearth method The molten metal is poured into a special mold and compressed by hydraulic action applied to rams A pressure of more than 6 tons per square inch is used to get rid of blow-holes and to obtain a metal of high density This method also prevents "piping" and segregation of the various constituents, such as sulphur, phosphorus, and manganese

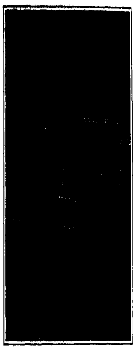


Lowering the heated chase hoop over the liner, upon which it will shrink in cooling.



Three tools for removing burrs and polishing the rifling of the gun.

draulic press enters largely into the work of manufacturing the 14-inch gun.



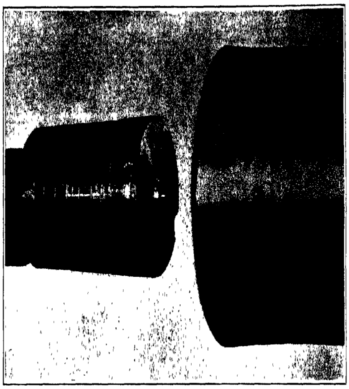
The chase hoop shrunk on and held in place during cooling by 500-ton jack.

The ingots are carefully reheated and forged to about one half of their original size This operation, according to naval requirements is performed after the casting has been rough drilled through its longitudinal axis. After forging the castings are gradually re-heated and annealed They are again heated, treated to an oil bath, and re-annealed The castings are now ready for delivery to the Naval Gun Factory in Washington When received there the castings are given exhaustive tests, and if found wanting, returned to the foundry as scrap

As the forgings are rough-drilled in the private foundry they are ready for rough-turning when received at the gun factory. They are carried to the lathes by traveling cranes The breech end is gripped in several large jaws on the face plate and the muzzle end is gripped by a "pot center," a large iron ring having several arms screwing radially through it Thus the forgings are held upon live centers.

The operation of turning is comparatively simple Often as many as four or five tools are used at the same time, requiring two or three carriages Tools 1½ inches wide are used for finishing, and there is no difficulty in keeping the measurements within 0.001 of an inch

Boring requires much greater care than turning; for the action of the drill, or cutting tool, cannot be observed. Three cuts are usually required to bore the tube and hoops. For the first cut a hog bit, a half cylinder of iron with a steel tool protruding from its end, is used. The other cuts are made with a packed bit, a wooden cylinder with an ordinary cutting tool. The wooden cylinder is slightly larger than the hole cut by the tool This insures an even, true cut When bored, the tubes, jackets, and hoops are ready for assembling, that is, shrinking together



The boring tool with which the inner tube of the gun is bored out to the exact final dimensions before rifling.

The tube, which is slightly tapered to render easier its extraction after it has been worn out by firing, is lowered into the shrinking pit, breech-end up. It is connected with water mains and cold water is allowed to circulate within it This keeps its temperature normal and assists in cooling the jacket. The jacket is next lowered into the hot-air furnace, which is a vertical cylinder of gigantic proportions made of fire brick and asbestos It absorbs heat from hot air, which has been passed over petroleum burners in pipes. The hot air enters the furnace at the bottom, circulates about the casting and is drawn out at the top to be reheated.

Because of the immense size of the jacket it takes more than thirty-six hours to raise the temperature of the metal to 700 deg. Fahr., which is the highest temperature to which this metal can be raised without changing its form in any way. The jacket is taken from the furnace by the crane and carried above the shrinking pit, where it is heat-tested. Metal strips, which have melting points between 400 and 600 deg. Fahr., are passed over every foot of the jacket. These are extremely efficient thermometers. Guided by men with asbestos gloves and huge tongs, the jacket is lowered over the lining, or tube, to the required position. A cold water spray is directed against the points in the jacket where it should first cool. The remainder of the jacket cools unassisted. Should the jacket jam, it is immediately hoisted off, allowed to cool, the abrasions filed off and another trial made. When cool, the tube and the jacket, which have been firmly shrunk together, are hoisted out of the pit and carefully measured. The tube is gaged to determine how much compression has resulted from the operation.

Why guns are built in parts and shrunk together is easily explained. Steel is elastic. It will withstand a certain pressure, stretch so much, and return to its normal condition When the pressure is too great it stretches beyond its limit of elasticity and breaks. If this same steel can be compressed from without it will then require a force equal to the limit of elasticity of the steel, plus the value of the pressure causing compression of the steel, to break or permanently strain the steel.

In shrinking the tube, the jacket and the hoops together this compression is attained. Thus, to burst a modern gun it requires a force equal to the strength of the steel plus the compression.

In each case the outer hoop is heated and slipped over the inner one In the operation described above the inner diameter of the 14-inch jacket when cold is always a little smaller than the outside diameter of the tube over which it is shrunk. The jacket is expanded by heat. It slips over the tube. When it cools it contracts and compresses the tube, making it slightly smaller than it was before The amount by which the diameter is decreased is called the compression. The jacket is also slightly enlarged by the process, but not beyond its limit of elasticity, so that it aways retains the tendency to return to its normal position.

It was found, especially in making the large gun, that it was much easier to bore the jacket and hoops first and to adjust the others parts to them than it was to try and fit the great inside boring to certain castings. The jacket fits over the breech half of the gun. The chase hoop fits over the muzzle half. By the same process the chase hoop is shrunk on next to the jacket. A locking hoop is next shrunk on over the joint of the jacket and chase hoops. Five smaller hoops are shrunk on the 14-inch gun before it is ready for finishing.

The gun is carefully drilled or bored and turned in the great lathes. The muzzle is finished by hand. The screw box is made in a collar. Formerly it was made in a jacket. This renders possible a change of screw box should the threads of the breech become worn. The collar fits tightly against the jacket and tube. This prevents the tube from moving to the rear.

Rifling gives the shell a rotary motion about its axis, which tends to keep its axis in the true line of flight. Rotation of the obtained as the result of a band of copper, firmly fixed to ll, being forced into the grooves as soon as the shell starts the gun. The grooves are spiral cuts in the lining of the n the 14-inch gun the grooves are uniform in twist. They to a depth of about one twentieth of an inch, and are someder near the muzzle than at the breech. The grooves e a circle in about twenty-four calibers. In the 14- s this gives the shell one twist in 28 feet. Thus, out its trip through the air the shell revolves once 28 feet covered. The groove is cut from the muzzle a cutting machine similar to a lathe.

ore is "lapped" with three sets of tools as shown in ompanying photograph. Emery and oil are used Lapping removes burrs caused by grooving.

of New Arctic Islands.—The overnment has decided on the following names for the three islands north of Siberia discovered by Lieut. Vilkitskii (Wilkitsky) last summer. The large island north of Cape Chelyuskin, the coast of which was followed for a distance of about 200 miles, is to be called Emperor Nicholas Land; the smaller island, lying south of this, Czarevitch Alexis Island; and the small island discovered northeast of the New Siberian Islands and southeast of Bennett Island, will be named for its discoverer, Vilkitskii Island.

The U. S. Government as a Map Publisher

THE Superintendent of Documents has just published a revised edition of his Price List 53, "Maps Published by the United States Government." The great number and varied character of the maps listed in this pamphlet is the more surprising in view of the fact that it is really far from being a complete list of the maps published by the Government, but merely an enumeration of those offered for sale by the Superintendent of Documents The four great Government map publishers—the Geological Survey, Coast and Geodetic Survey, Hydrographic Office, and Post Office Department—sell their own maps, and are not represented in this pamphlet, and the same is true of a few other map-publishing offices, such as the Mississippi River Commission Americans who are fond of patriotic superlatives may rest assured that the United States Government is, collectively, the greatest map-publishing institution in the world What is much more important, the maps issued by our Government compare favorably in workmanship with the best cartographic productions of foreign countries—a fact that helps to make amends for the disgracefully crude and inaccurate maps contained in most of the American-made atlases offered for sale in our book-shops.

How Long Has an Animal Been Dead?

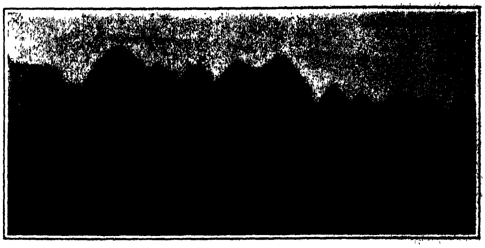
THE time of an animal's death and thus the age of meat is determined by E Lenk by a new method, which consists in noticing the variations in weight undergone by placing animals' flesh in water or saline solution, and he thus observes modifications which the microscope or chemical methods fail to reveal. Examining the weight of a piece of fresh muscle, he finds a continuous increase of weight up to 30 hours after the animal's death. After this the muscle loses not only the water it had absorbed, but also a part of its own The progress of the muscle's swelling is related to the establishment or relaxation of the cadaveric rigidity When the muscle takes up water, this is due to absorption of water by the biocolloids, caused by production of lactic acid after death As this lactic acid becomes concentrated in the muscle, the albuminoid substances which become reduced to the state of flakes, become incapable of retaining the water absorbed The process of unswelling which follows corresponds to the relaxation of cadaveric rigidity He finds that the nature of the liquid used, and also osmotic pressure, enter in here, and it is known that lactic acid production after death makes a complete change in osmosis While the osmotic pressure of living muscle corresponds to a 1 per cent common salt solution, it requires a 30 per cent solution to compensate the osmotic pressure of meat of a certain age, such as is found in commerce Such a method has an interest for food analysis and legal medicine.

Cover Your Bottles With Leather

IN carrying a small bottle, for instance, of medicine on a voyage, it is an excellent plan to make a leather covering for it, and this is easily done In this way if the bottle breaks there is no danger from wounds caused by the glass, and the cover acts as a good protector For a square section bottle, trace the profile on a piece of leather four times side by side, and add the small square representing the bottom, to one of the profiles. Cutting out with the scissors, this makes only one seam at the end to be sewed up, also the parts at the neck of the bottle, and the bottom piece.

Where People Live in Hives

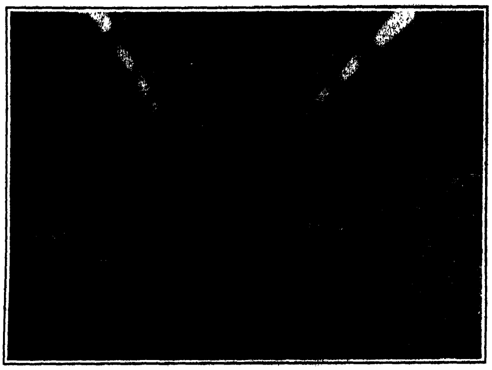
IN Mesopotamia the traveler sees a quaint form of dwelling, built of mud bricks in the form of a hive. Villages and whole towns in this peculiar form of architecture are met with. As the country is destitute of trees from which to hew rafters, and also devoid, in parts, of stone, the natives build their habitations of sun-dried mud bricks with high steep domes, similar in shape to a bee-hive. Our illustration depicts one of these bee-hive villages not far from Aleppo, on the route of the famous Bagdad Railway. Each home consists of several of these hives standing near together, and surrounded by a wall of similar material. One or more are used to live in, another for the animals, and still another serves as a granary, and so on, according to the possessions of the proprietor. One dwelling is seen without its outer covering of clay. The smaller conical piles are of dried manure, used for fuel.



Mesolmeleh, a "bee-hive" village, near Aleppo, Syria.

Safety Campaign Car

SENDING a "Safety First" campaign car over its entire lines, and instructing its employees in safeguarding not only their own lives, but the lives of the public as well, is the latest development in the campaign of safety waged by the New York Central Railway. This is the first instance of such an exhibit traveling in a railroad car, and the instruction given through its equipment is doing much to decrease accidents. The car has been in operation but a few months, and already records show that there have been thirty-five fewer employees killed while on duty than for the same period of last year. This, of course, covers the entire system of the road. As an educational feature, the car is especially interesting to the general public as well as to the employees of the railroad. Its lessons are all strongly impressed upon the minds of the onlookers, by a system of "Seeing is believing." Models of all machinery used by the company are shown, together with the right and wrong method of guarding dangerous parts. Photographs on one side of the car picture to the audience unsafe practices of railroad employees. The trespass danger is very forcibly shown by a number of photographs illustrating how persons risk their lives needlessly walking on railroad property. Above these pictures is a statement calling attention to the fact that no less than ten thousand such danger-defying people are killed on the roads of this country each year. One model of especial interest is that of the modern freight car with all its up-to-date mechanism and safety appliances. Attached to the exhibit car is a coach to be used as the lecture room, and this is equipped with a stereopticon by means of which illustrated lectures on safety are given to the men employed by the road.



Railroad car fitted up as a traveling exhibit of safety appliances.

A Giant of the Foundry

THE casting shown in the illustration is the low-pressure cylinder of a Corliss engine having a stroke of 5 feet and bore of 7 feet 2 inches. It is a single piece of iron, weighing 90,000 pounds. Some idea of its size can be obtained from the fact that a man of more than average height standing within the cylinder can just reach the top with the tips of his fingers, while the four shop helpers can easily crawl through the openings for its great valves. Those who are at all familiar with the trials that beset the molder can form some idea of the extreme difficulty in making a casting of such dimensions and weight. The steam ports indicated by the position of the right hand of the man to the extreme left of the illustration, required the most elaborate coring, and this particular piece of work was a most difficult operation.

Low-pressure cylinder of a Corliss engine—a 90,000-pound casting.

The [illegible]

IN a recent number of [illegible] upon the invention of [illegible] the utilization of translucent [illegible] of opal or ground glass for [illegible] name "marble light" does not [illegible] for we do not speak of a [illegible]. However, the [illegible] a better designation [illegible] not more complicated can [illegible] be found.

That marble in thin plates, particularly the colored varieties of marble, render it possible to obtain very beautiful effects has long been known, but the difficulty of producing thin marble sheets at a low price has made it impossible to utilise the discovery in a practical way. Latterly, a Hamburg engineer, W. Engel, has succeeded in making marble plates varying in thickness from 8 to 20 millimeters by means of a special grinding and saturating process. It is said that his marble plates permit a greater amount of light to pass through than ordinary frosted glass plates.

The marble plates are first ground down on both sides, and afterward saturated in oils of various kinds at high pressures and temperatures. Very beautiful effects are produced which it is said can hardly be obtained with colored glass.

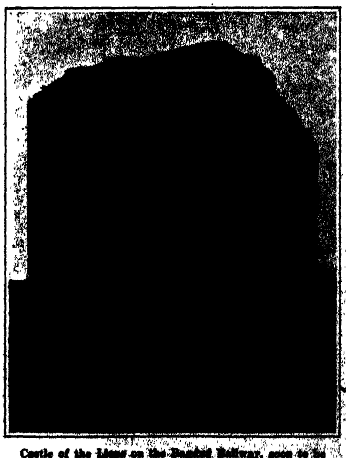
But pure white marble plates are also made, which, it seems likely, will compete successfully with opal glass. Less light is absorbed than with glass, and the color obtained is more agreeable. Most opal glass imparts to the light a greenish hue, the tint of the light which passes through the marble plate is rather a reddish violet, and, therefore, much more agreeable.

Caprifying Smyrna Figs

THE annual report of the Bureau of Plant Industry announces an important discovery in connection with the cultivation of Smyrna figs; viz., that the caprifigs may be carried over winter indoors if packed in boxes alternating with layers of sand. This discovery assures to the fig grower a supply of caprifigs regardless of the severity of the winter.

Old Crusader Tower to Be Demolished

JUST outside the Syrian port of Tripoli, lying alongside the railway track, is a famous old fort, known as the Tower of the Lions, from the tradition that it was built by Richard the Lion-Hearted, of England. As a matter of fact, it is one of six such forts built by the Crusaders to protect the coast, only one other of which exists, and which is in a poor condition. Now the Tower of Lions is to be demolished to make room for the railway, much to the discomfiture of archæologists who would like to see this old tower preserved as a relic of antiquity.



Castle of the Lions on the Bagdad Railway, soon to be torn down.

Switzerland has four coöperative associations for the growing and marketing of forest products.

New European Designs in Aeroplanes

The Short Folding-Wing Sea-Plane; Three New French Flying Machines

By European Correspondents of the SCIENTIFIC AMERICAN

Three New French Aeroplanes

By John Jay Ide (Paris)

The Ruby Torpedo

OVER two years ago there appeared in France a machine which sounded a new note in monoplane design. This aeroplane, the Tatin-Paulhan torpedo, was distinguished by the fact that the screw, at the extreme rear, was driven through a long shaft by a motor placed in the body behind the pilot's seat. From various causes the Tatin-Paulhan, although perhaps the most efficient machine of its day, was not placed on the market. Louis Paulhan soon turned his attention to Curtiss hydro-aeroplanes, which, however, have since been taken out of his hands.

In response to the desire of the French government for armed aeroplanes several manufacturers have reverted to the Tatin design which permits mounting a gun in the bow. The Borel firm exhibited a machine of this type at the last show in Paris. Unfortunately, owing to lack of orders, the Borel factory is at present closed down. Meanwhile a new "torpedo"—the Ruby—has made its appearance. The fuselage of this machine is of the usual box girder type, tapering toward the bow and stern. The wings are of Blériot section. The empennage is "floating," i. e., it carries no load, being perfectly flat above and below. The elevator flaps have their rear edges cut out to allow room for the propeller. Two unbalanced rudders form the terminations of two fins which, like the horizontal tail surfaces, are triangular in shape.

The landing carriage is composed of two pairs of V struts from which the axle is sprung by means of rubber shock absorbers. It will be seen that the lower wing cables are not attached to the chassis, but to a bottom pylon similar to the upper one. This is a very good feature. On too many machines wing cables are still anchored to the chassis. The danger of doing this comes from the fact that the pilot may crack a chassis strut and go up again without having it repaired.

The spectator is at once struck with the great height of the fuselage above the ground. This is needed to give the propeller sufficient clearance. Also in order to bring the machine to a stop within a reasonable distance the axis of the fuselage is inclined so that the nose is considerably higher than the stern. This, however, is not enough to render the braking effect comparable to that of a standard type monoplane. The great height moreover renders landing on rough ground a rather delicate proceeding attended with some risk of overturning. It may be said that the necessary height of the fuselage is the one great inherent defect in the "torpedo" class of monoplane; the only possible remedy would be to replace the propeller by a Coanda turbine propulsor. The cooling of the motor—an 80 horse-power Gnôme—has been found perfectly satisfactory, thanks to the louvers for the admission and exhaustion of air. Small points to be noted are the neat mica wind-shield for the protection of the pilot, and the aluminium cone effecting the final "run off" of the propeller boss. The span of the "Ruby" is 29 feet 6 inches and length 23 feet.

The F. B. A. Flying Boat.

This hydro-aeroplane, produced by the Franco-British Association, is a development of the Donnet-Lévêque, with which André Beaumont did so much flying in 1912. The company, which was formed last year, also manufactures the Curtiss and d'Artois sea-planes. The creation of this company was an eminently sensible way of solving the difficulty presented by the fact that Curtiss held patents covering the "flying boat," a term used to designate a hydro-aeroplane having a central float serving as a fuselage.

Particular care has been taken in designing the shape of the hull in order to reduce skin friction to a minimum. In this respect the new F. B. A. is an improvement even over the machine exhibited at the Paris Show last winter. It will be noticed that the deck forward has a slight overhang to prevent water being shipped. The ports for inspecting the compartments in the hull can also be seen. The dimensions are somewhat smaller than those of the [illegible] machine, which had [illegible] feet [illegible] inches span and 25 feet [illegible] inches length. The [illegible] horse-power Gnôme motor can be started from the pilot's seat. The controls are standard, i. e., a universally [illegible] lever works the elevator and ailerons, and a foot bar is used for [illegible]

The Bleriot "Total Vision" Monoplane.

This machine, the latest production of Louis Blériot, and shown at the recent Olympia Show in London, resembles the classic "XI," ~~except that~~ the wings are raised above the fuselage to the level of the pilot's eyes. The pilot can see downward as well as if the plane were above him, and also, by merely turning his eyes upward, can see anything overhead. It would be difficult to overestimate the importance of having a clear field of vision both above and below, which has hitherto been unobtainable on tractor monoplanes.

The credit for this innovation belongs to a French military aviator, Lieut. Gouin In the machine with which he has been experimenting he has also incorporated a system of air braking, modifying the wing section and rudder for the purpose. The wings present the ordinary Blériot section near the fuselage, but their angle progressively diminishes toward the extremities, where it becomes zero. The axis of rotation of the rudder forms the summit of a dihedral angle, which in normal flight is closed. When a braking effect is desired the rudder is opened out by a foot-operated control. The braking effect is, of course, proportioned to the opening of the dihedral angle. This feature is especially useful at the moment of landing, as it causes the machine to quickly come to a stop. A Blériot type Gouin has been entered in the Concours pour la Securité en Aeroplane. In the Blériot license Gouin, as the ordinary total vision type is called, the air braking feature is not incorporated.

Owing to the raised position of the wings the lower wing cables work at a more favorable angle than before. The pylon is of the standard "XI" type, but raised on four struts. A two-seater tandem "XI" bis with the total vision feature is now being completed by the Blériot firm.

It will be noticed that Blériot has thought fit to preserve the landing carriage in its original form. This member of the new monocoque is considerably smaller and has, therefore, much less wind resistance While retaining his original chassis Blériot has at last given up the well-known "cloche" control. The wing warping and elevator are now controlled through a vertical lever mounted on a longitudinal rocking shaft. This shaft carries at its rear end a sprocket connected by chain to another sprocket on the lower end of the bottom pylon On the same shaft as the pylon sprocket there is a pulley around which pass the warping wires. The elevator control wires are fastened directly to the vertical lever. The rudder is operated as before by a foot bar. Following are particulars of the Blériot total vision machine: Span, 30 feet 2 inches, length, 25 feet 6 inches; area of main plane, 104 square feet; weight (empty), 682 pounds; useful load, 309 pounds; motor, 80 horse-power Gnôme; tractor, Chauvière; speed, 68.2 miles per hour

The Short Folding-Wing Sea-Plane of the British Navy

By Major H. Bannerman-Phillips (London)

WHILE Great Britain has marked time too long since the disaster which befell her first large rigid naval airship at Barrow in 1911, and is only now beginning to make some headway with lighter-than-air vessels for oversea work, she has by close attention to detail on the part of constructors and devotion to duty on that of the naval personnel of all ranks concerned with flying, taken the lead in sea-flying, and the latest development of the Short sea-plane marks a long step forward in the matter of equipment for naval aviation. The radius of action of the sea-plane is at present limited, whereas that of the large rigid airship of the Zeppelin type may be put at 750 miles, and communication by wireless over 300 miles has been accomplished; but if the plan be adopted for working the sea-plane from a ship, the actual radius is not so important as it would be otherwise. There are, of course, three main difficulties to overcome in the care of sea-planes using the vessel of war to which they are attached as their base. The first is the question of stowage on board ship; the second, that of starting; and the third, that of alighting or being hoisted on board. It has been suggested as an alternative to this that a sea-plane accompanying a fleet should be fully sea-worthy and capable of riding out bad weather if it should be unable to reach land by its own power. Apart

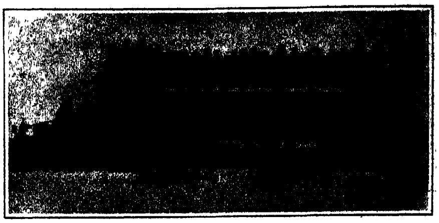
Historic Omnibus "Motorized"

THE accompanying photograph shows an old omnibus which plied between the Centennial Exposition and the City Hall, Philadelphia, Pa., in '76, being drawn by ten horses and carrying loads of from sixty to one hundred passengers The old 'bus has been doing service in Brooklyn for the past thirty-five years with picnic parties and holiday excursionists. It has just been "motorized" with a tractor. In spite of its great age this old vehicle has been well kept, and is in a remarkably well preserved condition; in fact, it is still so serviceable that its owner proposes sending it overland along the Lincoln Highway route to the Pacific Coast to run between the heart of San Francisco and the Panama Exposition.



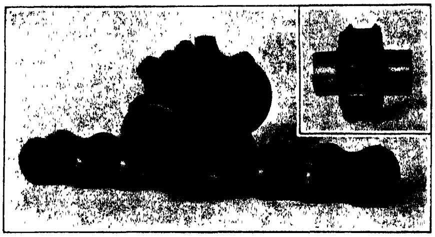
Centennial Exposition omnibus now equipped with a motor tractor.

Indian School of Tropical Medicine

THE American consul at Calcutta reports that the corner stone of the new School of Tropical Medicine at that place was laid on February 24th by the Lieutenant Governor of Bengal, and the institution is likely to be ready to begin work [illegible]. This school will have unique advantages for carrying on its special line of work; viz., the study of tropical diseases, with a view to finding more accurate methods of diagnosis and treatment. Such diseases are responsible for more than one third the mortality in the city of Calcutta. From the consul's report it appears that the new institution aims to become an international center in its particular field, students will be welcomed from all parts of the world, and medical research institutions in other countries are urged to establish scholarships at the Calcutta school, or to provide otherwise for sending research students to enjoy the advantages it offers. Inquiries should be addressed to Lieutenant Colonel Leonard Rogers, I. M. S., Medical College, Calcutta.

Simple Flexible Coupling

A VERY simple flexible coupling has recently been invented which consists merely of two sprocket wheels held together by a roller chain The sprocket wheels are keyed to the shafts that are to be connected, and then the coupling is readily effected by wrapping the roller chain about the two sprockets and clasping the chain with a master link. The shafts may as readily be disconnected. The coupling has great strength because all the teeth are in contact with the chain rollers at one time. A roller bearing, instead of sliding contact is thus provided The chain adjusts itself automatically to all variations of alinement within wide limitations. The coupling has no projecting parts, and hence it meets with all legal requirements for safety.



Flexible coupling consisting of two sprockets and a roller chain.

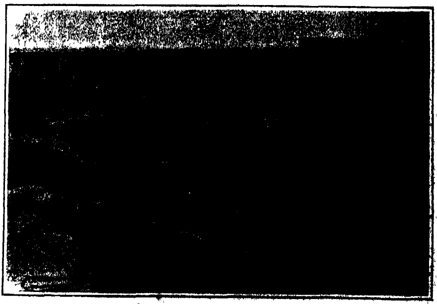
The New First Assistant Patent Commissioner

THE vacancy caused by the death of Mr. Robert T. Frazier will be filled by James T Newton, at present Assistant Commissioner in the Patent Office. On April 24th President Wilson confirmed Mr Newton's appointment as First Assistant Commissioner of Patents. Mr. Newton was appointed to the Patent Office March 25th, 1901, as an assistant examiner. Later he became examiner, and on November 14th last was promoted to the position of Assistant Commissioner.

Mr. Robert T Whitehead of Virginia has been appointed Assistant Commissioner of Patents by the President Mr Whitehead entered the Patent Office as an assistant examiner on February 1st, 1902, and was made a law examiner July 1st, 1909

Motor Car Converted Into Railroad Tractor

MULES proved unsatisfactory in hauling materials about the site for the Marconi wireless telegraph station at Kahuku, near Honolulu, Hawaii, and an old automobile in which the engine was quite sound was resurrected from a life of uselessness and remodeled as shown in the accompanying illustration for use as a narrow-gage railroad tractor. It can readily haul a number of cars. Prompt response with its three speeds forward and reverse has gained this tractor the favor of the workmen, to whom mule power proved as much of a hindrance as a help.



Motor car tractor in Hawaii.

Cottonseed Flour as a Possible Food for Man

By C. A. Wells

ONE of the earliest reported cases of the use of cottonseed flour as a food for man was that in which bread and other articles of food prepared from cottonseed meal were served certain members of the Farmers' Congress held at College Station, Texas, about fifteen years ago. Since that time a number of reports have been made of the use of the meal in human diets

Allison states that many of the smaller cottonseed oil mills of the country are manufacturing so-called "cottonseed flour" and that some of the large mills are producing and disposing of it with profit. It is not manufactured by any secret process, but is simply cottonseed meal of choice color, taste and odor which has been finely ground and thoroughly bolted. As might be expected, therefore, it contains more protein and less crude fiber than cottonseed meal of similar grade and origin. In other respects the chemical composition of the two is essentially the same. The terms "cottonseed flour" and "cottonseed meal" are used synonymously throughout this paper.

Cottonseed flour contains little kneading principle and more than twice as much protein as meat In order, therefore, to facilitate the making of bread and at the same time reduce the protein content of the latter, the flour is usually mixed with some other substance such as wheat flour. Most of the cottonseed flour bakery products found on the market are prepared in this way.

In 1012 there were crushed in the United States 4,921,073 tons of cottonseed equivalent to about 2,160,000 tons of meal. If we make the reasonable assumption that cottonseed meal has a digestibility of 70, then on the basis of the food values one ton of meal has a protein calorific food value of $[illegible] and a total calorific food value of $[illegible]. [illegible] one half of the annual production [illegible] the remaining half was fed to stock or used in making fertilizers. The Interstate Cottonseed [illegible] Association arbitrarily classifies cottonseed meal into three grades: choice, prime and off grades. Choice meal is from choice cottonseed finely ground. It must be perfectly sound, sweet, and of a light yellow color, free from excess of lint and hulls. It might be inferred that meal of this grade would be suitable for human consumption. Unfortunately, however, we have no record of the quantity of each grade of meal manufactured, so that one has no accurate data upon which to base a calculation of the amount of meal even presumably of a grade fit for man's use as a food. On the percentage basis, however, if cottonseed meal can be used as a food for man, and if it has a digestibility coefficient of 70 or greater, then 10 per cent of the meal produced annually in the United States (10 per cent of 2,160,000) would have a total calorific food value of $119,959,920 and a protein value of $106,920,000 (216,000 multiplied by $555.37 and $495.60, respectively). The same meal when fed to stock or used as a fertilizer would have a value not exceeding $6,480,000 (216,000 × $30.00, a liberal commercial value of one ton of meal).

Allison, Thompson, and others state that it is a suitable food stuff for man and that in many cases its continued use has proven highly beneficial. According to Fraps, "we have no reason to believe that cottonseed flour will not be a wholesome food, when used in small amounts to replace meats, or to reinforce a diet poor in flesh food," yet he says further, "we are inclined to believe that the maximum amount of cottonseed meal which should enter into the diet is two to three ounces per day; that the conditions under which such a diet may prove injurious must be established; . . . and that only experience and experiments can tell us the part which cottonseed flour should play in nutrition and under what conditions it may prove unwholesome." The writer has eaten for some time in his own home cakes and bread of various kinds containing a portion of cottonseed flour without experiencing any ill effects from its use.

It should be said, however, that while there are no reported cases of injury from the use of the meal as a food for man, it is possible and indeed quite probable that this is due to its so far limited use for this purpose. The assumption of its unwholesomeness for man naturally grows out of the well known injurious effects which it produces when fed to stock. Investigations are now under way to ascertain the true nature of cottonseed meal toxicity. If this can be done, cottonseed meal or flour may be given to the world as a new and exceedingly inexpensive food with an almost unlimited source.

"Snow Mushrooms"

THIS name is applied by Dr. Vaughan Cornish, in his recent book on "Waves of Sand and Snow," to some remarkable snow formations observed by him in traveling through the Selkirk Mountains, in western Canada. The railway passes through a pine forest, in which many trees have been cut at a height of about 6 feet from the ground. On the tops of the stumps, which are about 2 feet in diameter, snow collects in an overhanging cap like that of a mushroom. These caps, which sag at the border, and rise in a dome in the middle, are generally about 9 feet in diameter; i. e., they project 3½ feet beyond the stumps all around. Of hundreds observed by Dr. Cornish, all were perfect, none having broken with their own weight. Some of them must weigh more than a ton. Several photographs of these curious mushroom-like formations are shown. The whole phenomenon calls for exceptional meteorological conditions, and in this respect is analogous to the "snow garlands" described and illustrated in the SCIENTIFIC AMERICAN of January 27th, 1912.

The Forests of Norway are mostly in private or municipal ownership, the nation owning 28.5 per cent of the total forest area. The national forests of the United States occupy only about twenty per cent of the total forest area of the country.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

MUNN & COMPANY

AGENCIES WANTED

OLD ESTABLISHED London Firm seeks agencies for Patented articles and novelties, or representation of American Firms of good standing. Bickmann Limited, Huggin Lane, Queen Victoria St., London, England.

BUSINESS OPPORTUNITIES

WE INVITE CORRESPONDENCE with patentees of articles having merit, who wish to exploit or sell patent rights in Europe. We have special facilities in Germany. Address, Merit, Box 773, New York.

PATENTS FOR SALE

FOR SALE.—All patents on new windmill, in successful operation two years. References as to practicability. Best offer takes patents. Inquire Nicholaus Wagner, Notus, Idaho.

U. S. PATENT STOVE LID LIFTER. Cold handle that never gets hot. Meritorious device. Terms reasonable. For further particulars address Ray S. Crocker, Wellington, Ohio.

POSITION WANTED

AN EXPERIENCED TEACHER of Technical English wishes a permanent position in connection with a first-class Engineering or Mining School. Excellent references. Teacher, Box 773, New York.

SCIENTIFIC APPARATUS

GLASS APPARATUS, thermometers for scientific and industrial laboratories, surgical glassware, experimental work. For further particulars address Laboratory Supply Co., 125 State St., Rochester N.Y.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry *may* be repeated.

Munn & Co., Inc.

Inquiry No. 9351. Wanted to make some article out of wood which could be made from 2 inch ash, by party having 75,000 or more feet of waste per year which is now used for fuel.

Inquiry No. 9352. Wanted the name and address of a person who is in a position to get the state or county agency for articles of merit that can be sold to business houses or others at $5.00 or over. No kitchen utensils desired.

Inquiry No. 9353. Wanted the name and address of a manufacturer who can make flexible oil cans.

Inquiry No. 9354. Wanted the name and address of a manufacturer of a machine which will stitch silk around small metal rings.

Inquiry No. 9355. Wanted the name and address of the maker of triplex glass.

Inquiry No. 9356. Wanted the name and address of a manufacturer who can build an automobile wheel, also a *cigar sanding machine.* Concerns in the Middle West preferred.

Inquiry No. 9357. Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather.

Inquiry No. 9359. Wanted the name and address of a firm that makes razor blades for all makes of safety razors.

Inquiry No. 9360. Wanted the name and address of parties making pipe fittings such as ferrules, stems and bowls such as could be used in the making up of calabash pipes for smoking.

Inquiry No. 9361. Wanted to buy a Nut Cracking Machine, especially good for pecans.

Inquiry No. 9362. Wanted the name and address of the makers of a machine for splicing ties.

Inquiry No. 9363. Wanted the names and addresses of manufacturers of machinery for printing on intaglio copper plates.

Inquiry No. 9364. Wanted the name and address of buyer of mica in a crude state.

Inquiry No. 9365. Wanted the name and address of a manufacturer of machinery for embossing tin foil as is used in packing cigarettes.

Inquiry No. 9366. Wanted the name and address of a manufacturer of wire wheels, front axles complete with steering or [illegible], light sheet metal bodies, [illegible] with [illegible], pressed steel frames, [illegible], motors of the two-cylinder opposed type, cushions and many smaller parts for cycle cars.

Inquiry No. 9367. Wanted the name and address of a manufacturer of an automobile [illegible] machine.

Inquiry No. 9368. Wanted the name and address of [illegible] manufacturers or glass blowers who can manufacture a glass bottle and package it with [illegible], in large quantities for export, to sell at a popular price.

Inquiry No. 9369. Wanted the names and addresses of [illegible]. [illegible]

[illegible]

NEW BOOKS, ETC.

NAVAL WARFARE. By James R. Thursfield, M.A. With an Introduction by Rear-Admiral Sir Charles L. Ottley, K.C.M.G., C.B., M.V.O. New York: G. P. Putnam's Sons, 1913. 16mo.; 151 pp. Price, 40 cents net.

"Naval Warfare" is sufficiently technical without being tedious. Very few men, even among the well informed, know anything of even the broadest principles of the conduct of sea fighting, although these principles are, as Sir Charles Ottley says, precisely the same to-day as they were at Salamis and Lepanto. The little work briefly but very readably discusses the command of the sea, disputed command, invasion, commerce in war, and the differentiation, distribution and supply of naval force. It is the vote of the civilian that provides or withholds ships and munitions of war, and it is the duty of every civilian so to familiarize himself with the basic conditions of success in warfare that his influence may be exerted intelligently. Prof. Thursfield's manual, if universally read, would greatly forward this happy consummation.

COAL TAR DISTILLATION. And Working Up of Tar Products. By Arthur R. Warnes. New York: D. Van Nostrand Company, 1914. 8vo.; 185 pp.; illustrated. Price, $2.50 net.

The complex mixture known as coal tar is the basis of a very considerable industry, and a compact, up-to-date work dealing with the industry in its many phases will be appreciated by students, managers of plants and technologists. In brief but informative chapters, the author discusses the various processes used in distillation, in the recovery of acids, benzols and pyridine acids, and in the manufacture of such products as crude naphthalene and anthracene. Tar works' tests are given in the final chapter. Throughout the text figures are tabled for change-over points, temperatures and results. These are taken from actual practice, and will be helpful in a large degree, though the author warns the student that coal tar and its distillates are variable mediums, and processes that have succeeded in some instances might have to be modified in others.

INCANDESCENT ELECTRIC LAMPS. And Their Application. By Daniel H. Ogley. New York: Longmans, Green & Co., 1914. 12mo.; 107 pp.; illustrated. Price, 80 cents net.

Recent improvements in electrical lighting mean chiefly improvements in the filament. The semi-popular handbook offered in "Incandescent Electric Lamps" eliminates much phraseology that has been unintelligible to the layman, and aims at filling "the obvious gap." Illumination and its measurement, standard light sources, light distribution, the eye and the principles of vision—these captions give some idea of the discussions involved. Direct and indirect lighting systems are explained and contrasted, and it is hoped that the general reader may profit to the extent of acquiring such information as may enable him to select the best instalment *for his own particular needs.*

THE SHIPPING WORLD YEAR BOOK. 1914. Edited by Major Jones. London: The "Shipping World" Offices. 8vo.; 1912 pp. Price, $4.

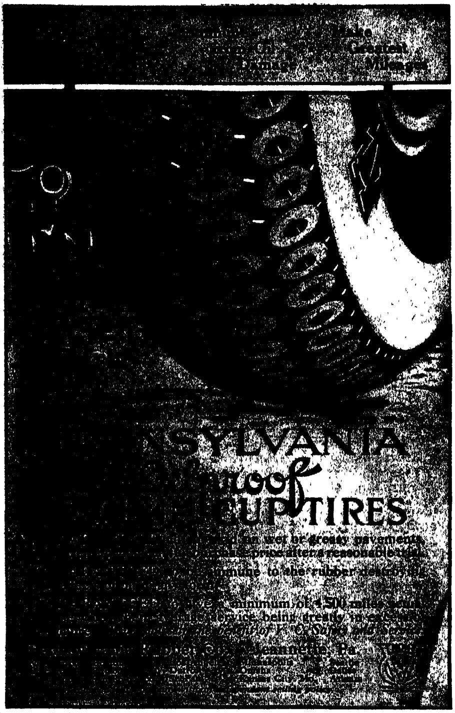
The "Year Book" is issued as a desk manual in trade, commerce and navigation, and is too well known to require a lengthy description. It is packed from cover to cover with thousands of facts having a direct bearing on the shipping business. Prominent among its offerings are the tariffs of all nations, a complete port and harbor directory of the British Isles and a directory of all the commercial ports of the world, with particulars as to accommodation, charges, tides, trades, pilotage and towage. Bartholomew's latest map of the world is, as usual, a feature of the new edition, and shows in distinguishing colors steamship and railway routes the world over.

THE FERTILITY OF THE SOIL. By Edward J. Russell, D.Sc. (Lond.) Director of the Rothamsted Experiment Station. New York: G. P. Putnam's Sons, 1913. 16mo.; 128 pp.; illustrated. Price, 40 cents net.

No grower can afford to ignore the basic processes of plant growth and the attainment of maximum fertility for his ground. In this little volume close attention is given to means for raising the fertility limit, and the illustrations show striking results. Partial sterilization, by toluol or by heat, effects a marvelous increase in crop. The six vital requirements—moisture, air, heat, nourishment, root room and freedom from harmful factors—are intelligently discussed. Phosphates are, of course, given the attention they deserve.

MOUNTAINS. Their Origin, Growth and Decay. By James Geikie, LL.D., D.C.L., F.R.S. New York: D. Van Nostrand Company, 1914. 8vo.; 311 pp.; illustrated. Price, $4 net.

The author is peculiarly successful in conveying hard facts in a pleasurable manner without catering to sensationalism on the one hand or losing the average reader by technical intricacy on the other. His discourse classifies mountains as original or tectonic—including the volcanic and epigene types of accumulation mountains—and subsequent or relict mountains. It is the borderland of geology and geography through which we are guided so masterfully in this fascinating journey of exploration. We investigate old Scottish volcanoes and glacial and aeolian hills; we study the architecture of the Alps; we plumb the submarine [illegible] of the Pacific. The many [illegible] accompanying the work are of a high order.



Do you know what this emblem stands for?

TRUTH

IT means bigger, better, cleaner business. It is the inspiring insignia of 140 clubs, with a membership of over 10,000 earnest men. Learn what the Associated Advertising Clubs of America are doing for honesty in business; for more systematic, scientific and successful methods of distribution, advertising and salesmanship. Attend the Tenth Annual Convention of the A. A. C. of A.

TORONTO
JUNE 21-25, 1914

Interesting Program

The program for this great convention is comprehensive and diversified, covering every phase of modern merchandising. The sessions will be addressed by able, successful men; open meetings, devoted to a wide range of special topics, will give everybody a chance to ask questions and hear his own problems discussed by the men who have met and solved them.

Edward Mott Woolley

the famous writer on business topics, has made a study of the A. A. C. of A. and their work, as well as of the plans for the Toronto Convention. He has embodied the result in a little book, "The Story of Toronto". This book paints a graphic, inspiring picture of what this great movement signifies.

It will be sent free to all business men asking for it on their business stationery—together with detailed facts as to the convention program and rates for accommodations

"I've proved for myself what those Doctors say about Sanatogen"

THERE is tremendous weight in the written opinions of over 19,000 practising physicians. But the strongest proof for *you* is the proof of *your own* experience.

It is what Sanatogen does in nourishing *your* exhausted nerves, in giving *you* better sleep, appetite, digestion and energy, that will give you the greatest confidence.

Your decision—today—to try Sanatogen, is a decision to prove for yourself that what so many American and European physicians and so *many* active, thinking professional men and women have said about Sanatogen's service, may apply with equal force and blessing to YOU.

Sanatogen is sold by good druggists everywhere in three sizes, from $1.00.

Sanatogen received the Grand Prize at the International Congress of Medicine, London, 1913

Prof. Thos. B. Stillman, M.S. Ph. D.
The well known research chemist of New York, writes:
"The chemical union of the constituents of Sanatogen is a true one, representative of the highest skill in the formation of a product containing phosphorus in the organic phosphate condition, and so combined that digestion and assimilation of Sanatogen are rendered complete with the greatest ease."

Sir Gilbert Parker, M.P
The eminent novelist-statesman writes from London
"Sanatogen is to my mind a true food tonic, feeding the nerves, increasing the energy and giving fresh vigor to the overworked body and mind"

Charles D. Sigsbee,
Rear Admiral, U S Navy, writes:
"After a thorough trial of Sanatogen, I am convinced of its merits as a food and tonic. Its beneficial effects are beyond doubt."

SEND for Elbert Hubbard's new book—"Health in the Making" Written in his attractive manner and filled with his shrewd philosophy together with capital advice on Sanatogen, health and contentment. It is free. Tear this off as a reminder to address

to which our attention is called. The numerous diagrams are carefully drawn, and such folding inserts as the bathyorographical map of the Pacific Ocean and the cross-sectional layouts of the southern uplands of Scotland are vastly instructive. Prof. Geikie is an adept at turning for us the captivating pages of the past and in giving us new eyes with which to view the present.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12989) G. H. asks 1. How much will a cubic foot of air weigh when compressed to 6,000 pounds on the square inch? A It will require four hundred atmospheres to produce a pressure of 6 000 pounds per square inch, and this will compress the air about four hundred times We say about, since Boyle's law is only approximately correct at high pressures. Air at normal pressure and the freezing point weighs 0 08071 pound per cubic foot At four hundred atmospheres a cubic foot will weigh four hundred times as much, or about 32 284 pounds. 2. How many parts of air will one part of liquid air make when evaporated? The idea being that it would be better to use liquid air than compressed air for certain purposes when desired to use such away from the compression plant A It requires about 800 cubic feet of ordinary air to make 1 cubic foot of liquid air This when evaporated will yield 800 cubic feet of air again If liquid air were retained in a closed vessel, the ultimate pressure would be about 12,000 pounds per square inch We should prefer to be elsewhere when this happened Liquid air is never kept in a closed vessel No railroad would receive it for transportation except in open vessels, so that evaporation can go on freely.

(12990) W. N. G asks: Would it be too much to ask of you to explain the cause of well-defined pictures of various objects such as ships, wrecks fine buildings, well-known landscapes and various other familiar things, which may be very long distances away, appearing in the frost on windows on very cold days? A scientific explanation of this very strange freak of nature would very much interest me, and probably all of your readers and subscribers A When we were children living in a region much colder than New York, we often saw shapes formed by the frost on the window pane, such as those you mention, but we never thought them real copies of objects beyond our horizon We thought them fancies of our imagination We do not now know any reason why they should be other than resemblances in the delicate tracery of the frost We have no scientific explanation for their being any more There is no possible way in which a ship could produce a picture of itself beyond its horizon

(12991) F C. S asks: Will you kindly inform me upon the following to the best of your ability? On my auto I have four new wheel caps that hold the wheels on the axles Those caps are made of hardened steel, the outside of which is nickel plated What is the reason, when these caps get wet and stand for a day, the nickel plate blisters and flakes off? These caps are new Is there anything I can do to the caps to prevent this action on the nickel, and why does the nickel plate blister and flake off hardened steel when it does not do so on other metals that are plated in the same solution? A The coating of nickel on the pieces of hardened steel does not have as good contact as it would upon soft steel or iron, nor is the nickel continuous It has pores in it, through which the moisture comes into contact with the steel, and steel rusts much quicker than iron. The great increase in the use of steel is not without its drawbacks Our galvanized iron and tin plates are no longer made of iron, but of steel, and they are by no means as durable, nor does the coating of zinc or tin adhere so strongly as it did upon the softer and more porous iron plates which were used before the steel processes were developed.

(12992) G. M asks: Is it possible to construct two vertical lines parallel to each other by means of a freely suspended plumb bob? A. It is not possible to construct two vertical lines by means of plumb lines near each other. Neither can vertical lines be strictly parallel to each other Vertical lines converge and meet at the center of the earth If two plumb bobs are hung near each other, neither will hang perfectly vertical They will draw each other slightly from the vertical by their gravitational attraction for each other. It was by an experiment of this sort that the earth was weighed. For this, see Young's "General Astronomy," page 110. We send the book for $3 05 postpaid.

(12993) P. P. C. asks: Will you kindly give me the proper explanation as to why, in moving pictures the wheels of vehicles seem to revolve backward? A. If the spokes of a wheel in a moving picture keep time with the exposures, so that the spokes are in the same position in all the pictures, the wheels will be seen to stand still on the screen. If the spokes succeed each other either faster or slower than the exposures of the film, the wheels will be seen to be turning forward or backward, as the case may be. We have observed all three phenomena. They do not always seem to revolve backward.

A Rare Opportunity for a Capable Inventor

By E. W. McCormack

THERE is at the present time an unusual opportunity for an inventor and a manufacturer, to place upon the market a device for which there exists a large demand. The device for which hundreds of firms are seeking, is one that will assist them in putting up their pay-rolls.

Everyone conversant with the subject realizes that the present method of analyzing the denominations of currency needed by cashiers and paymasters, is one of the most troublesome, inefficient and wasteful operations in connection with the weekly or semi-weekly pay-roll. What is needed is a device which will operate upon the principle of an adding machine, but instead of accumulating totals the device should be designed to segregate the amounts into the required denominations.

For illustration, if the first item on the pay-roll is $15.78, it requires a mental operation for the cashier to segregate, upon a separate list, the items which go to make up the amount, i. e., one $10 bill, one $5 bill, one 50-cent piece, one 25-cent piece, and three 1-cent pieces. The entire pay-roll is analyzed in this manner, so that when the pay-roll check is presented at the bank a memorandum accompanies it, calling for bills and coin in the following amounts:

106	$10.00	bills
71	5.00	bills
97	2.00	bills
313	1.00	bills
118	0.50	coins
63	0.25	coins
1,149	0.10	coins
211	0.05	coins
953	0.01	coins

Thousands of firms realize that they are wasting valuable hours, which yearly cost them hundreds of dollars, according to the size of their pay-roll, because there is no simple, efficient, labor-saving device which will enable them to add up the total of their pay-roll and segregate the items into the proper units. Many concerns have their cashiers guess at the amounts, and often their guesses are not good, but, however good the guesses, it simply means that the larger the pay-roll, the more pieces of money it is necessary to handle, because if guesses are made, more bills of smaller denominations must be specified than needed, consequently when two thirds through the pay-roll, it becomes necessary to pick up and count five one-dollar bills instead of having one five-dollar bill.

It should not be any great mechanical problem for an inventor to produce a combination adding machine and pay-roll device, so that the cashier could strike keys 15.78 and have the machine print a line similar to the following illustration:

Amount	$10 00	$5 00	$2.00	$1 00	50c.	25c	10c	5c.	1c.
15 78	1	1	.	. . .	1	1			3
20 15	2	. .	. .	.			1	1	
18 86	1	1	1	1	1	1	1		1
12 11	1	. . .	1				1		1
14 51	1	.	2	.	1				1
etc.	etc.	etc.	etc.	etc.	etc.	etc.	etc.	etc.	etc.
2131.73	106	71	97	313	118	63	1149	211	953

Such a device as this could be sold for $100 or $200, and the time saved would pay for the machine several times over in the course of a year, as the present method is slow and inaccurate, and, as before stated, one of the most troublesome problems in connection with the handling of pay-rolls.

This opportunity for an inventor is unusual because invariably the majority of inventions of an entirely new idea are ahead of the times, or in advance of actual demand for the device. Regardless of the merits of the invention, if there is no demand, it means that a great amount of educational work must be done before a market can be created. The cost of an efficient sales campaign, along educational lines, coming as it does directly after the experimental and manufacturing expense, is responsible for many disappointments and failures. In many cases it is the man who takes hold of the proposition after the ice has been broken who reaps the greatest financial reward; but, in this particular case, there is a demand already created, as firms are asking for, and willing to buy, such a device, and there is at present nothing to be obtained which will do the work.

New European Designs in Aeroplanes

(Concluded from page 401.)

from the difficulty of finding a suitable engine for such a machine, this would place serious limits to its action, and it might be on land and in its hangar just when most wanted by the vessels at sea; and as to riding out a storm, say under the lee of one of the warships, in the first place, even a boat-shaped hull of the size of a sea-plane, although without the top-hamper of wings, etc., could not be expected to stand all weathers, whereas the planes would offer such a surface to a storm as to make destruction certain. In the second place, the warship under whose lee it would take shelter would be seriously hampered by having to remain in position, since it might have to proceed elsewhere at speed.

It is obvious, therefore, that a sea-plane intended for use with a fleet must be "mothered" by a large vessel and able to not only start its reconnaissance flights from the ship as a base, but send back information while away, and at any time return to it for protection in case of bad weather and get taken on board

The Short folding-wing sea-plane goes far toward solving the problem of providing a machine which can fulfill these conditions. It is a tractor biplane and has a very wide and relatively shallow fuselage, rectangular in section, with ash longerons and spruce struts. The engine is a 100 horse-power 14-cylinder Gnôme, mounted in steel housings within the fuselage members, and surrounded by a sheet metal cowl with air-holes in the top front for cooling purposes, and on the top there is a chimney to carry away both the air and the exhaust gases The rounded engine cowl is carried back and tapered off into the fuselage proper behind the pilot's seat, being cut out and shaped to form a windscreen for both pilot and passenger At the rear of the fuselage is the empennage, consisting of a cambered fixed tail-plane, followed by divided elevator flaps, a fixed vertical fin and a balanced rudder

It will be some time before sufficient experience will have been gained in handling this type of machine on board a warship to say how far the arrangement for folding the wings is of advantage in lowering on the water surface and hoisting inboard, but it has the merit of simplicity, and there can be no doubt of the value of a system which permits of reducing a span of 60 feet to a width of 9 feet when stored in a hangar, a process which only takes a few minutes in this case

The patentees of the Short folding sea-plane maintain that by the use of such

BOWSER
Sold A Million

How Users of Gasolene and Lubricating Oils Save Money the Bowser Way

There is no problem of oil storage, utility and economy which Bowser cannot solve. From Bowser's invention of the Self-Measuring Oil Pump twenty-nine years ago, the Bowser idea has so developed that today Bowser Systems are used everywhere—from private garages to million dollar manufacturing concerns. There are over 500 different Bowser systems—more than a million users.

BOWSER OIL STORAGE SYSTEMS

Wherever oil is used there is need for a Bowser System—

In Garages Here Bowser tanks store the gasolene underground and keep it *full-powered*—away from dirt, evaporation, fire, theft, spillage or waste. *All* the gasolene is used—*and used full strength.* Pumps any distance to the garage—in exact predetermined quantities. All capacities. Easy to install.

Garage equipment also includes systems for the Public, Private and Commercial Garage—underground tanks—also above-ground units for both gasolene and lubricating oil. *Efficiency Compellers.* Time and money savers.

In Stores Oil merchandise stored the Bowser way is always safe, clean, full bodied—and kept apart from other merchandise A Bowser store system measures the oil and computes the price. No "mistakes." Soon pays for itself

In Factories From simple oil storage units to big centralized clarifying and circulating systems No oil wasted or lost. You can use the same oil over and over again

Ask Bowser Use the coupon—whether you're a garage owner, storekeeper or owner of a power plant. Let Bowser advise you. It means time, oil and money saved Twenty-nine years of Bowser experience may mean something to you. Use it. No cost or obligation in finding out. Sign and mail the coupon—NOW.

Wireless Telegraphy and Telephony

SIMPLY EXPLAINED

70 Pages
156 Illustrations
By ALFRED P. MORGAN
Price $1 00 Postpaid

The simplest, latest and most comprehensive popular work published on wireless, for the Wireless Operator, Amateur or Professional

THIS is undoubtedly one of the most comprehensive treatises on the subject, and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective, showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

A book the wireless experimenter cannot afford to be without. It enables one to design and construct apparatus Also valuable to the layman

MUNN & COMPANY, Inc., 361 Broadway, New York City

machines the requisite shed accommodation for an aeroplane base is reduced to one fifth or one seventh, and that this great saving in the cost of sheds will have the result of increasing the amount of money available for the purchase of machines. They also maintain that the value of the folding sea-plane was proved conclusively in the last British naval maneuvers in 1913, when a 160 horse-power Short folder sea-plane was carried on an ordinary warship without the slightest inconvenience (owing to its compactness) and was launched and reshipped many times without the slightest hitch, performing evolutions in rough weather in the North Sea, and that their invention has made possible the project of having an "aeroplane ship" or mother vessel to carry twenty to thirty machines, for which plans are already out.

A noticeable feature of the Short folder sea-plane is that the wings can be folded or spread out at will by the occupants of the machine, while it is floating on the water, a small winch being provided in the machine for this purpose, the whole operation being completed in two minutes. The same operation has been completed in the same time on land at the end of a 7-mile journey, during which the machine was "towed" by road with folded wings, but fully equipped and ready for flight so soon as the wings were spread. In the same way it is possible to carry the machine on board ship, hung in davits, fully equipped and ready to be launched at a moment's notice. Very special care has been taken in the design of the hinges and fastenings for the folder sea-planes and the seven tests to which the "short" machines have been put by the British Admiralty are understood to prove that the strength of the whole structure has been increased by the adoption of the folding-wing fittings.

Aeroplanes have, of course, been launched from special platforms on warships before now and alighted on them in similar fashion, but the carriage on deck of a machine of the ordinary type is obviously out of the question, and the taking down and putting together again for each flight would consume much valuable time; moreover, it would increase the wear and tear of the parts very considerably.

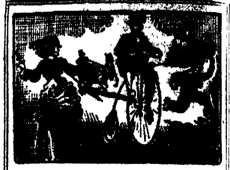
A Disastrous Colonizing Experiment

FOUR years ago a Russian company undertook to establish a permanent fishing colony in Nova Zembla, and transported thither about 100 persons—fishermen and their families—from Archangel. The colony flourished for a time and increased in numbers. It was visited at irregular intervals by vessels of the company, which supplied the settlers with provisions and took cargoes of fish back to Russia. Last year, however, the Winter set in earlier than usual and was very severe, so that vessels were prevented by the ice from carrying supplies to the fishermen. A scientific expedition which visited Nova Zembla last Summer made the shocking discovery that the whole colony had perished of hunger

Vulcanological Observatory in the West Indies

IT is proposed to establish on the island of St Vincent, West Indies, a vulcanological observatory and laboratory, as a memorial to Dr. Tempest Anderson, the distinguished English vulcanologist, who died last August while on his way home from a visit to the volcanoes of the East Indies. Dr. Anderson was sent by the Royal Society to make a study of Monts Pelé and Soufrière immediately after the eruptions of 1902, and also made subsequent studies of West Indian volcanoes.

Moving Pictures in the Army.—Every day brings to light new uses for kinematography. During the recent encampment of a brigade of cavalry near Winchester, Va., a number of new formations and evolutions were introduced. Moving pictures were taken of these movements and the films will be displayed at military posts for the instruction of officers and men.



Did You Ever Ride a High-Wheeler?

Those old-fashioned two-story bicycles were the gay deceivers, all right!

You needed a stepladder to mount one of them—and only half a second to get off. They never stood on ceremony when they got ready to buck.

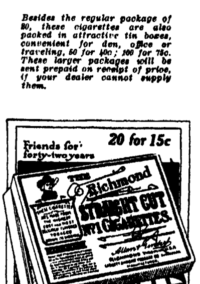
Seems an awful long time since they were the vogue. So long ago that the last of them must be in the museums by this time.

The encyclopedia says the first high-wheel bicycle was brought to this country from England in 1876.

That was five years after Richmond Straight Cuts were first introduced to the American public.

They both made a big success. But while the high-wheel bicycle is *gone* forever—Richmond Straight Cuts *go on* forever They will ever be the best of all Virginia Cigarettes.

Besides the regular package of 20, these cigarettes are also packed in attractive tin boxes, convenient for den, office or traveling, 50 for 40c; 100 for 75c. These larger packages will be sent prepaid on receipt of price, if your dealer cannot supply them.



SPARK COILS
AND THEIR CONSTRUCTION

160 describes the making of a 1½-inch spark coil and condenser.
1514 tells you how to make a coil for gas-engine ignition.
1522 explains fully the construction of a jump-spark coil and condenser for gas-engine ignition.
1124 describes the construction of a 6-inch spark coil.
1087 gives a full account of the making of an alternating current coil giving a 5-inch spark.
1527 describes a 4-inch spark coil and condenser.
1402 gives data for the construction of coils of a definite length of spark.

This set of seven papers will be supplied for 70c. Any single copy will be mailed for 10c.

Beacons for Airmen

Vol. CX. No. 20
May 16, 1914

Munn & Co., Inc., Publishers
New York, N. Y.

Price 10 Cents
$3.00 A Year

A Prize of

$1000.

For the best house of the year

In the interest of better homes *Country Life in America* offers a prize of a thousand dollars, which will be paid to the owner of that house, occupied for the first time within the year 1914, which, in the opinion of the judges, attains the greatest all-around excellence. It is hoped that the award will so justify itself as to cause this offer to be repeated year after year.

CONDITIONS

The house must be a country or suburban home, first occupied between Jan. 1, 1913 and Jan. 1, 1914. It must have cost not less than $5000, exclusive of the land and interior furnishings. It must be a year-round home, completely equipped with heating, plumbing, etc.

BASIS OF AWARD

It is intended that the best house of the year shall win the prize. The cost will not enter into the matter at all, so that a $5000 house will have just as much chance of winning as one costing many times that amount. To this end the entries will be judged on a point system, in which the 100 points representing perfection are divided as follows: plan, 35; exterior appearance, 25; interior equipment and furnishing, 25; setting (by which is meant the arrangement of paths, garden and planting in the immediate surroundings), 15.

ENTRY REQUIREMENTS

The competition is open to any house built on the North American continent conforming to the "conditions" above stated. (The owner need not necessarily be a subscriber to *Country Life in America.*) Each house must be represented to the judges with the following material, which shall be in the hands of the Competition Editor, *Country Life in America*, Garden City, L. I., on or before July 1, 1914: (1)—Plans of first and second floors in black on white paper, drawn to a given scale or dimensioned. (2)—Sketch block plan of house and immediate surroundings. (3)—At least 8 photographs, not smaller than 5 x 7 in., of which not less than three shall be of the exterior, nor less than one each of living-room, dining-room and owner's bedroom. (4)—A typewritten description of about 1000 words, supplementing the photographs and plans and describing materials, color schemes and special points of construction, arrangement and furnishing.

THE JUDGES

Mr. Guy Lowell, architect and landscape architect, of Boston; Mr. Howard Van Doren Shaw, architect, of Chicago, and the Editor of *Country Life in America* will be the judges. These three will designate the winner of the prize and will award honorable mention to such other houses entered as may in their opinion merit it.

$1000 to the owner—a gold medal to the architect

$1000 will be paid to the owner of the house selected as the best of those submitted. A gold medal, suitably engraved, will be awarded the architect of the same house.

Plans, descriptions and photographs entered will be returned only to those enclosing postage or express return charges. The material describing the prize-winning house will become the property of *Country Life in America*. The material describing houses awarded honorable mention may be retained and paid for at the magazine's regular rates.

The prize house and a number of those awarded honorable mention will be published in *Country Life in America*. "The Best House of the Year" appearing in the October (1914) Annual Building Number. Arrangements are now being made to exhibit photographs and plans of the successful houses in several of the larger cities.

Analyzing the Human Singing Voice

UNTIL the present day the nearest approach to accuracy in the gaging of musical tone has been afforded by the human ear. Those interested in the development of their own voices or of the voices of singers or students have been as dependent upon the not altogether faithful and infallible judgment obtained by the individual sense of hearing as the importer or distributor of tea or coffee is dependent upon the verdict of the professional sampler, or taster.

As the sense of taste is seldom exactly the same with two persons, and tea tasters will often be found to disagree as to the flavor and quality of a brand they may be sampling, so the sense of hearing is subject to disagreement—the more so, indeed, because its impressions are of a transitory nature and derived from abstract and not from physical subjects. This is shown by the indefinite terminology used by the voice teachers and critics in their work of vocal tone description. On the other hand, the sense of sight is held to be the most accurate and unfailing, because it has the advantage of a permanent material object that may be deliberately studied and analyzed. It is by far the most discriminating sense we have, and, therefore, impressions received through it are capable of exact description.

Photographic tone analysis is an ultra-modern device of science, which promises to exert a vital influence upon the development of the voice, as, indeed, it may, also, upon the manufacture of musical instruments. It is in the formulation of the theory of correct tone production that the exact analysis of tone by photography has accomplished its most valuable function thus far.

Dr. Floyd S. Muckey of New York city, who was associated with the late William Hallock, professor of physics at Columbia University, in a scientific investigation of the physical laws of the voice which lasted more than twenty years, has evolved a scientific method of voice production, a method which especially takes into consideration the factor of interference with the correct action of the voice mechanism. It is by photographic tone analysis that he specifically sets forth the part which interference plays in preventing the full use of the vocal capabilities. Interference is also shown to be the direct cause in the deterioration of the vocal instrument. He accomplishes his analysis of vocal tones, and, likewise, his analysis of instrumental tones by the use of the Koenig manometric flame analyzer which has been greatly improved for this work by Prof Hallock

The photographic "tone analyzer," as the apparatus might more popularly be termed, provides an actual and permanent record of tone quality and shows the definite convention of cause and effect between interference with the mechanism and the resulting tone How these tone photographs bear out the principles advocated by him is thus outlined by Dr. Muckey:

"The roof of the mouth ends posteriorly in the soft palate, which rises in the act of swallowing to prevent the entrance of food into the cavities of the upper pharynx and nose. If the soft palate is raised during voice production, these important cavities, constituting the larger part of the resonance space, are shut off and the apparatus records the loss of the four highest partial tones, showing a decided reduction in the strength of the pitch, or fundamental, tone A voice loses more than half its volume, i. e., its intensity and carrying power, by this great loss of resonance space. Any contraction of the muscles (*palato-pharyngei*) of the soft palate attached to the large cartilage of the larynx (*thyroid*) interferes with the pitch mechanism"

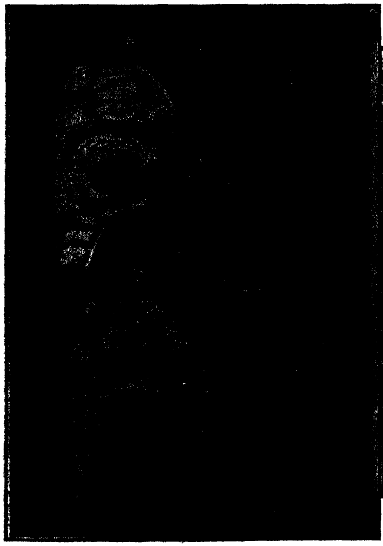
This apparatus photographs, not tone, but the vibratory effect of air-waves from the source of tone production, as projected through Helmholz spherical resonators, attuned to the fundamental and characteristic overtones, upon tiny jets of gas-flame whose fluctuations are caught by a camera lens The resulting impression recorded upon the photographic plate is a series of horizontal lines of light picturing the motion of the flames and accurately representing the vibrations of a single string tone, as divided into the fundamental tone and its six or seven overtones These make up the complex tone of any single tone sounded either by the voice or by a musical instrument of the string family

"The results of the operation of this apparatus are shown in the accompanying photograph of the vibrations of a vocal tone The lower C, as produced by the voice mechanism in the vowel "a" (as in "father"), upon the pitch of a standard fork (128 vibrations per second) is given. The number of vibrations that the fundamental tone bears to the rate of its overtones, harmonics, or upper partials, is in the ratio of 1 to 2, 3, 4, 5, 6, etc. Hence, the resonators are attuned to bass C, and its seven overtones, whose rates of vibration and approximate pitches are as follows:

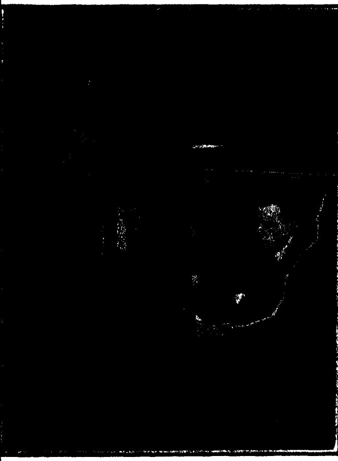
Fundamental,	128	vibrations	per	second,	about	bass C
1st overtone,	256	"	"	"	"	middle C
2nd "	384	"	"	"	"	" G
3rd "	512	"	"	"	"	high C
4th "	640	"	"	"	"	" E
5th "	768	"	"	"	"	" G
6th "	896	"	"	"	"	" B flat
7th "	1,024	"	"	"	"	C in alt.

"The analysis is made so that we may describe each

(*Continued on page 421*)

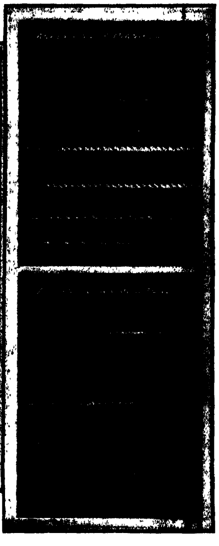


The effect of correct and incorrect placing of the soft palate is shown by the photographs of tones appearing opposite the mouths. Note that when the full resonance capacity of the nose is used, as in the upper picture, a strong fundamental tone with good overtones is obtained; the lower picture shows how markedly poor is the effect when the soft palate is up. The photographs of the fundamental tones and the corresponding overtones, appearing opposite each drawing of the human head, were obtained by means of the improved Koenig manometric flame apparatus shown in the center engraving on this page. They give instrumental evidence (better than any personal opinion) of the effect which the position of the soft palate has on tone production.



The Koenig manometric flame analyser consists of a number of Helmholtz resonators connected by tubes with gas jets As the subject tested sings, the flames vibrate They are reflected in the vertical mirror, which the operator can turn by hand, so that the vibrating flames are seen as in the photographs on the left hand side of this page. The mirror is not used in making the photographs; a plate holder in a camera is merely shifted laterally during exposure, thus producing the effect shown in our picture. Before the late Prof Hallock of Columbia University improved the Koenig manometric flame analyzer photographs such as those reproduced on this page could not be made Experimenters made drawings by watching the reflection of the flames in the mirror. The photographs herewith reproduced are among the first ever obtained by means of the Koenig apparatus.

Analysing the singing voice.



Tones of the pianoforte and violin, respectively, sounded upon lower C. In the piano record the fundamental tone represented by the first line is weak, but the overtones are highly developed. In the violin record the lower line, being bass C (128 vibrations), records no air waves, because air-waves of that length were not sounded; the second line is the octave of bass C (256 vibrations) and the fundamental of this set of partials.

The All-steel Aeroplane

IT is a curious anomaly that in this age of steel construction such a large amount of wood should be used in the building of aeroplanes In the sister art of yacht construction wood has been abandoned, except for a few uses, entirely in favor of steel and the high-grade alloys. Why has not a similar substitution been made in the aeroplane, where the demand for weight-saving is scarcely less insistent than it is in the racing yacht?

A few years ago it would have been near the truth to say that this clinging to wood construction was due to conservatism—an unwillingness to change from the familiar to the less familiar. The gliders of the early experimentalists were made of wood and canvas; so was Wilbur Wright's first power-driven machine; and in an art so novel as that of flying, whose votaries, generally speaking, were men possessed of more daring and enthusiasm than they were of technical knowledge, it can readily be understood that there was a disposition to cling to the forms and material, with which Wright made his classic flight at Kitty Hawk

Wright himself was not free from this prejudice in favor of wood for aeroplane construction. The writer remembers discussing with him at the Belmont Park meeting the subject of the SCIENTIFIC AMERICAN design for an all-steel racing monoplane. Wright acknowledged that the theory of the metal machine was correct; but turning to the "Baby Wright" machine which was standing nearby, he patted one of the wooden struts and voiced a sentiment which is strong, even to-day among aeroplane builders, by saying: "This is the material for the aeroplane; I know what it can do, and it gives some warning of a failure."

Yet, it is a fact which cannot be disputed, that compared on the score of strength for weight, and of reliability, the steel and other alloys are vastly superior to wood, even for such special requirements as those of the aeroplane.

The main transverse spars in the wings of a monoplane are not subjected to any more complicated and severe stresses than is the mast of a racing yacht. The compression in the spars, due to the pull of the guy wires, finds its counterpart in the compression of the mast due to the pull of the shrouds; and the transverse bending stresses, applied to the spars at the wing cross-ribs, find their counterpart in the bending stresses on the mast due to the pull of the mast hoops—yet the yacht designer has not hesitated to abandon the wooden mast and the wooden boom and substitute spars built up of steel.

We note that our esteemed contemporary, *The Engineer* of London, which has long been an earnest advocate, like ourselves, of the substitution of metal for wood in aeroplane construction, ascribes the reluctance to make the change largely to the difficulty of obtaining the shapes which are required for the framing, and particularly for the struts, as used in the biplane. There is no doubt that aeroplane construction calls and will ever call for unusual shapes. But it is certain that, as in the case of the automobile, when once the request for shapes of special metal and special form has become general, there will be a lowering in the price due to the increased demand.

Some Points in Cup Defender Construction

IT is probable that there is no structure built of metal in which the stresses are so complicated, or in which they approach so near to the breaking point, as in the modern steel-and-bronze yacht, and particularly in such yachts as are built for the "America's" cup contest. The hull of such a yacht consists of a steel frame, overlaid with a shell of bronze plating which is not much thicker than the outside cover of a good-sized book. The form of this hull has been calculated with the greatest nicety, and to secure the best speed results, it must, in spite of its fragility, be held true to form—there must be no distortion. The problem of making the yacht at once extremely light and extremely rigid is complicated by the fact that the heavy stresses to which it is subjected tending to distort, if not to pull it apart, are not distributed evenly throughout the boat, but are applied with great intensity at certain points of concentrated stress. Thus, there is the enormous upward pull of the shrouds applied at the side of the boat, and abreast of that the even heavier downward thrust of the mast, tending bodily to burst out the floor of the yacht at that point, and necessitating the construction of a widespread mast-step, to distribute the stress over a large area of the hull.

It is interesting to recall the fact that in the case of the first extremely light metal boat built for the defense of the cup, "Defender," during a knockdown in a squall, this very result of thrusting the mast through the floor came very near happening. The "Defender" was subsequently *strengthened* at this point by carrying wide steel straps from the foot of the mast to the channels at the junction of deck and side of hull

As we have said, every conceivable form of stress is applied to a racing yacht. The hull is subjected to severe alternations of compression and tension; and heavy torsional stresses, tending to twist the hull about its longitudinal axis, are applied when the yacht is heeled well down under her press of canvas. In the earlier metal boats the presence of these severe stresses was revealed by the frequency with which a rivet head would snap off, particularly when the yacht was heading into a sea; and it was not unusual under such circumstances for leakage to be quite severe. Indeed, we have heard it stated, and it is quite conceivable, that the inflow of water along the leaking seams, was at the bottom of the "Valkyrie"-"Defender" controversy in the days of Lord Dunraven.

However, with the steady improvement in the quality of materials available for hull construction and for standing and running gear, the yacht designer is, to-day, able to build with exceedingly light scantling. He may edge up very closely to the "factor-of-safety" line, without being harassed with the fear of breakdowns which haunted the designer of ten or fifteen years ago.

The New York County Medical Society and the Press

THE extent to which medical men may participate in the enlightenment of the public through newspapers and magazines has been the subject of discussion within the past few months. In New York city the Medical Society of the county, through its Board of Censors, has delivered a pronunciamento on infractions of the code of professional ethics, and there have been summoned before it physicians and surgeons of standing whose names have figured in popular articles where facts of medical or surgical progress have been obtained with their co-operation or at least their consent. Discipline also has been threatened practitioners who might be guilty of possible or even constructive indiscretions of publicity.

While something may thus have been accomplished toward checking the unwholesome self-advertisement to which many physicians, both great and small, have yielded, there is manifest a reactionary tendency toward suppression of information on medical topics. Every true scientific man must view with approbation the spread of sound and wholesome knowledge of hygiene and disease among people at large. If the New York County Medical Society persists in its present absurd policy it will only hinder the more general popular appreciation of physicians and surgeons as a class; it will withhold from the public a knowledge of scientific achievements and efforts.

That self-seeking practitioners, and not only charlatans and quacks, may acquire undeserved and fictitious newspaper reputation and be able to impose on a credulous public to its manifest detriment is so obvious that the medical profession should protect itself. But such abuses, real or fancied, should be judged solely on their own merits, instead of being connected with the dissemination of proper and correct medical intelligence. Because a reckless reporter has sinned that is no reason why conscientious writers for the press—men who take the trouble to have their writings approved before publication—should not continue to present information in a popular way. Why it is unethical for an American physician to have his name [illegible] in connection with an [illegible] cable dispatches from Europe [illegible] achievements of his fellow-workers [illegible] height of absurdity. So, too, the [illegible] in regard to work of high merit or [illegible] deep interest and concern to the public, [illegible] of the old high-priest days of science than of the twentieth century. If the laity were to receive authoritative, accurate, simply worded information as to progress in medicine, surgery, and hygiene, with the new and essential features emphasized, if safe and sane conclusions as to the future usefulness of new discoveries are drawn, who can question that a much more sympathetic attitude toward medicine would ensue and an appreciation of medical men more nearly approaching that found in Europe would be produced?

In spite of all the harm done by sensational publications there are many periodicals in which the discussion of medical topics could be carried on in a simple, healthful, and beneficent manner. But that is possible only if editors have the co-operation of the medical profession generally, and if their efforts to secure absolute accuracy and reliability are supported in greater part.

To-day scientific medicine depends upon the dictum of no authority whose *ipse dixit* is accepted with awe and reverence almost superstitious. Not the utterance of a man, but the demonstration of scientific truths in the careful regimen of the laboratory convinces in these scientific days. Once a discovery has been announced to the medical profession, once it has withstood the criticism of those competent to judge, it should be authoritatively brought to general attention. Only in this way can the public be interested to the point of rallying intelligently in support of physicians when the community is threatened by restrictive legislation or attempts to lower the standards of qualifications for practice.

From time to time the most promising efforts in scientific and experimental medicine, indicating results of great value, are interfered with by the efforts of zealous anti-vivisectionists and zoophilists with their attempts at legislative suppression or control of animal experimentation. Had those interested in scientific medicine ever properly informed the public of the nature and object of their experiments, even describing the necessary suffering in the few cases where it must occur, instead of permitting the spread of the general, but unfortunate impression that such practices take place only in cloistered seclusion without systematic method or oversight, no hysterical protests would avail against a community convinced of the great benefits resulting from the labors of those engaged in experimental medicine. The SCIENTIFIC AMERICAN holds no brief for newspaper science, sensationalism, or the commercial exploitation of scientific men and methods, but it does protest against any policy that prevents the result of any scientific investigation, medical or otherwise, being kept from the general discussion of people of intelligence in the columns of journals whose responsible editors make every effort to secure accuracy, authenticity, and sanity for their articles. American medical men must learn that only by the widest knowledge of their efforts and work can they gain the public esteem, while it is only through such knowledge that the higher standards they aim at will be not only appreciated, but generally demanded and enforced.

A Notice

FROM time to time we have had occasion to call attention to the fact that the SCIENTIFIC AMERICAN is not connected in any *way* with the organization entitled, the "Scientific American Compiling Department," engaged in the sale of the Encyclopedia Americana. This notice is published owing to the fact that we frequently receive letters of inquiry in regard to that enterprise, in spite of the notices published in our columns from time to time stating that we are not responsible *for any* statements that may be made by the above-mentioned company or its *alter ego*, the Americana Company. The history of the case and of the long-drawn-out lawsuit in connection with the matter were explained at some length in the SCIENTIFIC AMERICAN of November 8th, 1913. It is because of the continued use of the name contrary to our wish that we feel constrained to again advise our friends and readers of these facts.

German Machinery Imports and Exports for the Last Year.—During 1913 the machinery importation into Germany from all nations totaled about [illegible] tons, divided as to the principal countries as follows: United States, 40 per cent; Great Britain, 24 per cent; [illegible], 7 per cent; Switzerland, 6 per cent, etc. There were imported [illegible] tons of agricultural machinery, representing 44 per cent; 7,500 tons of [illegible] boilers, [illegible] tons of railway and street cars [illegible] and [illegible] tons of motor vehicles.

[illegible]

L[illegible].—[illegible] to [illegible] railway [illegible] New Zealand [illegible] 126 miles in length. [illegible] of its mountainous character, New Zealand is known to be one of the most difficult countries for the construction of railways. Its lines are full of sharp curves and unusually heavy grades.

Preliminary Trial Trip of "Vaterland."—On her first sea test, which lasted for two days, the new Hamburg-American liner "Vaterland" of 58,000 tons, the largest ship in the world, is reported to have made the high average speed of 25.8 knots per hour, with the high output of 90,000 horse-power from her four turbines. Both her owners and her builders, Messrs. Blohm and Voss, are to be congratulated that the ship has so greatly exceeded her contract speed.

Japanese Dreadnought "Fuso."—If the *Marine Rundschau* is correct in stating that the Japanese superdreadnought "Fuso" was recently launched with her engines and guns in place, it seems likely that the Japanese navy will be the first to have a battleship in commission carrying twelve 14-inch guns. This ship is of about 30,000 tons displacement, and she will have a secondary battery of sixteen 6-inch rapid fire guns. She is down for completion in July, 1915, and a sister ship, also building in Japan, is due to be completed a year later.

Population and Traffic Problem.—Great as is the scale upon which the New York subways are being enlarged, it must be admitted that the recent census statistics indicate that the system will be in urgent demand long before it is finished. Figures given out recently from the census office show that on July 1st of this year New York's population will be about 5,333,537 people, which represents a gain in four years of 556,664. This means that the city, large as it is, is now adding to its numbers every year some 140,000 souls, which is the population of a large city.

Hydraulic Grader for Culebra Cut.—A hydraulic grader for smoothing down the slopes of the Culebra Cut has been constructed for the Isthmian Canal Commission. The grader is an arrangement of high-pressure boilers and pumps, which will pump water from alongside the vessel and deliver it at high pressure to pipe lines or hose for sluicing material down at the banks of the canal. This is the kind of work that is being done at Cucuracha slide by pipe-line suction dredge No. 82, which is pumping to two monitors at a discharge pressure of 45 to 50 pounds. The new graders will deliver at a pressure of 225 to 235 pounds to the square inch, discharging through a three-inch hose at an elevation of 50 feet above the water-line.

Large Turbine Air Compressors.—By utilising the energy of rapidly-rotating bladed wheels it is now possible to compress air on the turbine principle to much better advantage, it is claimed, than with piston machines. The rotary type, such as is constructed at the Berlin Allgemeine Works, now goes as high as 3,000,000 cubic feet an hour and compresses to 10 or 12 atmospheres, taking about 12,000 horse-power in a single machine. A special steam turbine is coupled to three separate rotary air compressors. Between each compressor is a cooler for lowering the temperature of the air. The Victoria Falls and Transvaal Power Company appears to be the first to take advantage of the large-unit construction afforded by the present type, and is installing a large plant for power transmission by compressed air, having already in the central station near Johannesburg as many as 12 turbo-compressors of 4,000 horse-power size. Air is sent in 20 miles of pipe to 17 mines for drills and other uses. With the three new 12,000 horse-power sets which are to be put in, the total will be 84,000 horse-power transmitted to the mines.

City Takes Title to Steinway Tube.—Title to the Steinway tunnel, which has been the source of much litigation for years, passed to the city recently. The deed was received by the Mayor from the Interborough Rapid Transit Company, which acquired it some years ago through the absorption of the company owning it. The litigation was as to whether, the franchise for the tunnel having expired, the company would be able to operate it by reason of special legislation. The city won and the company decided to turn the tube over to the city for [illegible]. The cost was in the neighborhood of [illegible]. The tunnel is to be a part of the dual rapid transit system, and the Interborough will be credited with [illegible] as its share in its [illegible] in the entire system. The Board of Estimate approved the contract with the Rapid Transit Construction Company for the completion of the [illegible] pending the completion of [illegible] work will be started soon. The [illegible] Grand Central Station [illegible] in Long Island City.

Electricity

Wireless Telephony from Brussels to Paris.—The London *Times* reports that on March 29th a tenor singing in a concert at Laeken, near Brussels, was heard by wireless telephony on the Eiffel Tower, in Paris. The distance between the two places is 225 miles. Use was made in this experiment of a new microphone invented by the Italian engineer Marzi.

A Railway from Limbach to Mittweida is one of the most recent electric lines in Germany, and is designed to connect these industrial towns and also Burgstädt, taking in many smaller localities, so that the present region of Saxony will have better communication than before. The line is 15 miles long and is fed by the Oberlungwitz electric station. An overhead trolley line working at 1,000 volts supplies the cars, each of which carries two motors of 50 horse-power. Freight as well as passengers is carried on the trains, and there is already a good traffic assured. It makes connection with the state railroad which crosses the electric line at two points.

A Novel Advertising Device has made its appearance, which consists of a polished metal cylinder shaped like a vase. Inside the receptacle is a small electric motor which makes a magnet turn about a shaft. Small articles for sale with pieces of iron imbedded in them are put on the cylinder, and the magnet causes them to travel around the surface. This movement attracts the attention of the passers-by, and still further attraction is caused by employing small figures of men or others of an amusing character which go through irregular evolutions around the cylinder. Small steel balls with flags stuck in them are found among the best for this use.

Electrical Iron and Steel Production in Sweden has been on the increase within a recent period. As to the amount turned out in that country, starting with 122 tons in 1908, it rose to 870 tons in 1910 and 18,000 tons in 1912, or the last report. There are upwards of 20 electric furnaces running at present, using in all some 60,000 horse-power. New furnaces are building at Lofoten, Gelivara and Sandviken. The Stora Kopparberga Company recently purchased a waterfall which gives 150,000 horse-power, and is to build new furnaces in the near future. As regards chrome steel, a new plant was put in use not long ago at Trolhattan with two electric furnaces, which reduce ore imported from New Caledonia and South Africa, using the three-phase system. The product contains from 5 to 9 per cent chromium, and is furnished in four different grades.

The Failure of "Hail-Rods" in France.—Reference has been made several times in these columns to the recent erection in many parts of France of large lightning-rods, known as "electric Niagaras," supposed to be efficacious in averting hailstorms. The futility of such devices seems obvious to persons familiar with the mechanism of thunderstorms, of which hail is merely a by-product, yet hundreds of the rods have been installed at great expense. In a recent communication to the National Society of Agriculture of France, Prof. Alfred Angot, director of the French meteorological service, after pointing out the absurdity of the "Niagaras" from a scientific point of view, cited a number of instances in which the rods had signally failed of their purpose. Thus, the large rod installed on the Eiffel Tower has not had any effect on the frequency of hail in its vicinity. In the suburbs of Clermont-Ferrand a big "Niagara" stands on an iron tower 100 feet high. This rod was itself pelted with hail twice in 1912 and four times in 1913; in one storm some of the hailstones attained the size of hen's eggs. Similar cases have been reported from other parts of France.

Electric Automaton.—M. Torres Quevedo, a well-known Spanish engineer, is occupied with some very interesting inventions in the new government mechanical laboratory at Madrid, of which he is the head. His idea is to be able to operate various kinds of machines on the automatic principle and to a much greater extent than is done at present, largely by the use of electricity, and thus the machine is to do without the workman in numerous cases. It is commonly supposed that an automatic machine must do the allotted work in exactly the same way, but the object proposed by the inventor is to make a machine imitate a human being in carrying out complicated operations implying a choice, where the circumstances in the case are very numerous. To demonstrate this by a special case, he has already constructed an automatic chess player which is reduced to simple terms and makes use of two pieces, while the opponent uses one piece and can move at will. The machine in turn determines the proper move, and carries it out by the mechanism, so that the machine is obliged to provide for a very great choice in making its movements. Another interesting apparatus is an automatic calculator, and, unlike most machines of this class, it is first set at the required figures and then carries out all the needed movements for making the calculation without any manual aid. M. Torres Quevedo is engaged upon a device of this kind, and has already made working models to demonstrate the principles involved.

Science

A Fluorescent Microscope.—Mr. Karl Reichert of Vienna, has constructed a fluorescent microscope which is of advantage in certain cases. The lighting of the object to be observed is effected by provoking its fluorescence by means of ultra-violet rays. The ultra-violet rays, having passed through one of the new light filters of Wood, are concentrated by a quartz lens on the object to be examined. The advantage of this method is that the color of the fluorescent light provoked by the action of the ultra-violet rays varies in general with the chemical nature of the fluorescent object. In this way it is possible to recognize differences in the matter and composition of objects which are not perceptible by ordinary light. It also enables the physiological action of ultra-violet light on living organisms to be studied.

Ocean Temperatures and Icebergs.—The Bureau of Standards has recently issued a bulletin by C. W. Waidner, H. C. Dickinson and J. J. Crowe, on "Observations on Ocean Temperatures in the Vicinity of Icebergs and in Other Parts of the Ocean." The records of sea-water temperatures obtained by means of an electrical resistance thermometer and a Leeds and Northrup temperature recorder installed on the U. S. steamships "Chester" and "Birmingham" in their patrol of the North Atlantic Ocean show that the temperature variations in parts of the ocean far removed from ice are often as great as in the neighborhood of icebergs. This disagrees with the observations of Prof. Barnes. "In view of the differences in the character of the records obtained by Barnes and ourselves," the authors state, "it is very desirable that further observations be made in different parts of the ocean, and under as varied conditions as possible before attempting to draw final conclusions."

The Imperial Bureau of Entomology, conducted under the auspices of the British Colonial Office, is becoming one of the great humanitarian institutions of the British Empire, especially on account of its work in connection with disease-carrying insects. All the British colonies contribute to the expense of the Bureau's work and share in its benefits. During the year 1913 one task carried out was the collecting and collating of the laws and regulations relating to injurious insects in force in the various parts of the Empire. During the same year, 80,000 specimens of insects were received by the Bureau, *of which 14,000 were blood-sucking insects*. An urgent problem now impending is to safeguard India from the importation of the yellow fever mosquito; a contingency threatened by the shifting of trade routes that will follow the opening of the Panama Canal. It is believed that yellow fever has already appeared in New Caledonia. A careful mosquito survey has just been carried out in Hong Kong.

Radium in the Upper Atmosphere.—Hess, of the Vienna Radium Institute, has recently published the results of some remarkable experiments. He has investigated the penetrating radiation which occurs in the upper atmosphere by means of balloon ascents, and he arrives at the startling conclusion that at a height exceeding 2,000 meters there is a rapid increase in the intensity of the penetrating rays. At these heights the penetrating rays from the earth itself would be absolutely negligible, while that from the radium emanation in the air, which has its origin in the earth and is of limited life, must be, at any rate, less than at the surface. So that it would seem we must assume some extra-terrestrial source for these radiations. The conclusion that a great part of the penetrating radiation cannot come from the known radio-active constituents of the earth and atmosphere is one that must evoke general interest, and calls for the further radio-active exploration of the upper atmosphere.

The Electron as a Vibrating Particle.—Herr Korn has established, during a period of over twelve years, a mechanical theory of gravity and of reciprocal molecular effects, the main points of the theory being as follows: Suppose an infinite and incompressible medium, with very rapid vibrations, containing slightly compressible particles; such a system is capable of an infinite number of different vibrations. The mathematical investigation of such a system is not difficult, provided that we assume no whirlpools to exist. The fundamental vibration will be a pulsation of the particles and Newton's Law of Gravitation will express the reciprocal effects of these particles, due to this fundamental vibration. If we impose on the vibrating particles the condition of constant velocity of pulsation, the electrons may be considered as such pulsating particles. In other words, we must conceive the electrons to oppose a very great resistance to any external action tending to modify their velocity of pulsation; it is also necessary to admit that these extremely rapid vibrations emit very little or no radiation. The duration of the vibrations is extremely great in comparison to the duration of all vibrations hitherto known.

Some Interesting Automobile Novelties

A Funeral Motor Car

A SAN FRANCISCO undertaker has built a funeral car that is far more than a hearse, for, in addition to the space for the casket and flowers, there are accommodations for thirty-seven people.

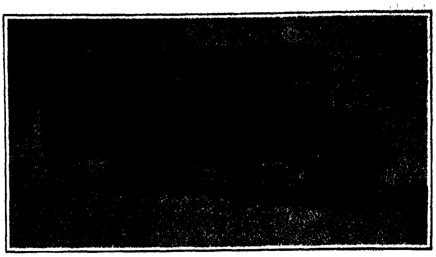
A single vehicle, therefore, may take the place of a whole funeral train. The car is built on a five-ton standard truck chassis. The woodwork is solid mahogany and it is upholstered with 8-inch morocco leather cushions. It is fitted with electric lights and fans, and rivals a parlor car in comfort and elegance. The car is 30 feet long, 10 feet wide, and 18 feet high. In order that it may be able to make the sharp turns in the aisles of the cemeteries, the wheels are cut under.

The Army Automobile in Service

AN armored automobile was lately given some actual work in operations in Morocco, this belonging to the Spanish army. The present car is provided with an especially thick plating, and it covers the whole of a large power car so as to give it the appearance of a square van. Steel plate is used which is said to be proof against usual bullets. The new car is a veritable traveling fortress, and is divided into three parts, the front for the driver, the middle part, which contains the firing outfit and has slit windows with flaps, and the back portion, fitted out as an ammunition hold. On the top of the car are double flap doors which open nearly the entire roof in order to give an outlook, and there are small side windows also placed near the roof for lookout purposes. The main lookout window is in the front end of the car, and above the driver's seat.

The Auto Skiff

FROM the very earliest days of boat building it was realized that the body of a vessel must be shaped to cut through the water readily; but with the design of vehicles on land little thought was given to air resistance until very recently, when our high-speed machines have shown us that air resistance is an important factor. We are beginning to realize that fuel costs may be kept down if our automobiles are designed to plow through the air with a minimum of head and skin friction. More attention has been paid to this abroad than in this country. Automobile bodies are growing more and more like boats Logically, the smaller the engine the more necessary it is to pay attention to streamlines in the car body. The accompanying photograph shows a small foreign car which is so boatlike that it even carries a short mast and flag at the stern Great care has been taken to maintain the lines of the body undisturbed. The steps are kept wholly unencumbered. The tool chest and extra shoes and tires are inclosed in a compartment in the rear. With the motor mounted directly above the single front wheel, weight is reduced to a minimum, and the car is capable of attaining very high speed



Funeral motor car with compartment for the casket and seats for 37 passengers.

Interior of the car, showing the mourners' section.

Three-wheeled motor car with boat-shaped body.

A Small Diesel Engine

NUMEROUS attempts have been made to produce an oil engine on the Diesel principle, but of small size, such as is demanded for common use, especially for small dynamo groups, but up to the present time the problem seemed to be unsolved. While it is true that the gasoline motor has come into good use for this purpose, its application is limited owing to the cost of fuel, and also danger from fire. Another type of motor using the incandescent tube ignition operates on the same economical fuel as the Diesel engine, but it consumes much more fuel, and the engine is larger and heavier than the Diesel, besides having other disadvantages. Recently the well-known Berlin Allgemeine works has produced a small motor for use with dynamos, ranging from 60 to 200 horse-power sizes. Economy in fuel consumption, good governing within wide limits, and excellent combustion, as shown by the quality of exhaust gas, is secured in the new engine when using a compression of 30 to 40 atmospheres. It employs a special air compressor which furnishes 60 atmospheres for the motor starting and for injecting of combustible. An oil pump supplies the proper quantities of oil at each interval, working in connection with an atomising valve. Another point is the starting by means of compressed air. All the parts are designed so as to be easily operated by ordinary personnel. Small groups of this kind have an all-inclosed dynamo mounted on one side of the motor, and this gives a compact makeup. Compressed air comes from a small pump on the motor, and air is stored up in a cylinder in the base, the oil tank being also lodged here. The present engines run at 500 revolutions per minute. On the whole the present makeup is likely to give a wider scope for the use of the Diesel engine, especially for electric groups.

Motor Car for Transporting Horses

EDMOND BLANC of Monaco, a well-known sportsman, has found that his horses suffered on the journey from the stables in England to the Riviera and return, because of the frequent transfer from railway car to boat, and from boat to car. This had the effect of rendering them nervous, and their performances at the race track were not up to par. The necessity of devising some means of transporting the animals without changing cars was evident. This led to the design of the portable stable shown in the accompanying photograph. It consists of a motor truck body, which may be lifted off the chassis and put aboard a train or a boat as the case may be, without disturbing the horse inside. The interior of the car, as shown in one of the photographs, is well padded inside to protect the horse against injury, and the sides are fitted with shutters to provide ventilation. The horse does not feel the fatigue of travel so long as he does not have to leave his stable.

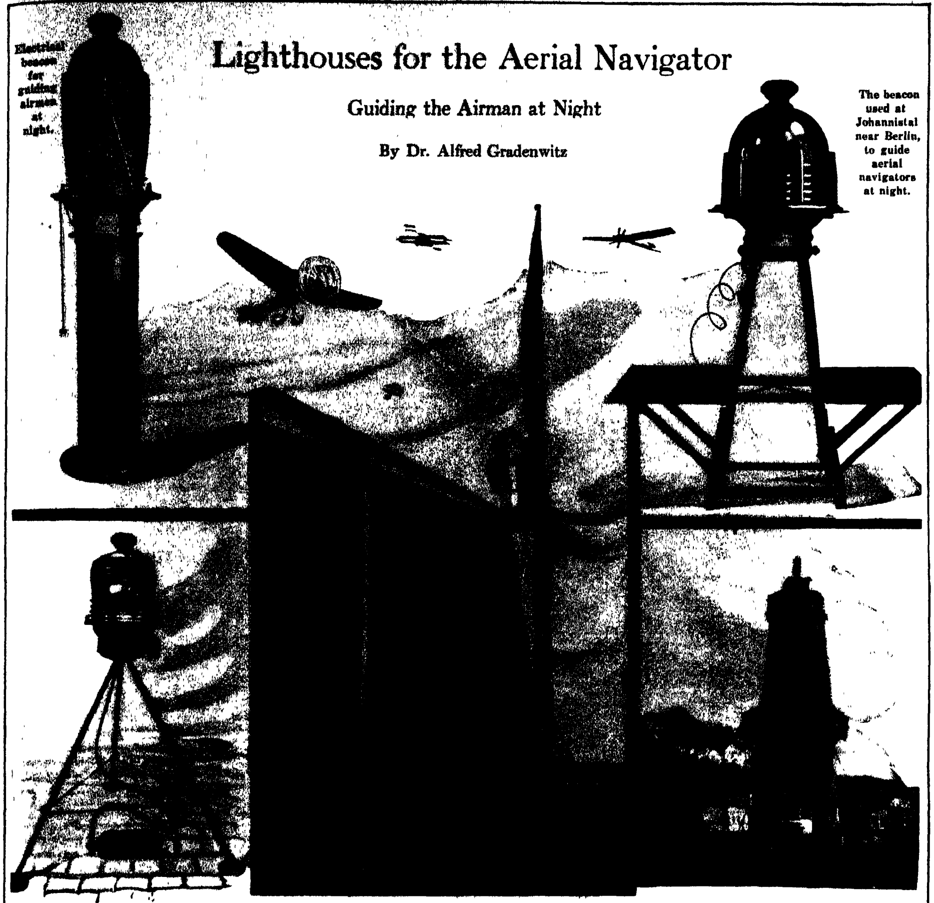
Lighthouses for the Aerial Navigator

Guiding the Airman at Night

By Dr. Alfred Gradenwitz



Electrical beacon for guiding airmen at night.

The beacon used at Johannistal near Berlin, to guide aerial navigators at night.

Portable military gas beacon.

The beacon used at Potsdam.

A lighthouse for the Johannistal airmen.

Light signal known as mark 45.

Light signal known as mark 123.

Light signal known as mark 1242.

THE use of fires to inform the navigator at dark and in foggy weather of the proximity of the coast and of his actual position can be dated back to the days of Grecian antiquity. In ancient times torches were lighted or heaps of logs burnt, but our inventive age has produced beacons in which the rays from various sources of light are reinforced by mirrors and lenses. These beacons, in accordance with the rapid strides made by navigation, have lately been developed to extraordinary perfection and variety.

The airman requires a similar means to find his way in the atmospheric ocean as navigators at sea. Whereas the light from beacons in the sea need be seen only in a practically horizontal direction, lights for aerial navigation must so give out their beams as to be visible from any point of space situated above the lowest flying level.

A Berlin firm has for some years been engaged in experimental work destined to produce special types of searchlight for aerial navigation. The first type of aerial beacon which they evolved was a stationary apparatus radiating freely in an upward direction beams of light coming from the upper hemisphere, whereas the beams from the lower hemisphere were deflected in a practically horizontal direction by a set of prisms. The type eventually developed, however, comprises several belts of lenses, sending out uniformly in all directions the beams of a lamp placed in the focus.

A point was made from the outset so to design these intermittent beacons as to allow each place to be distinguished from any other by some characteristic mark. Each aerial beacon must have a distinctive mark of its own, this being the only means of reducing the risk of the aeronaut's losing his way. Such marks are made up of variable successions of light flashes denoting given figures.

These characteristic flashes enable the aeronaut with the aid of his log-book, at a moment's notice to ascertain the place where the beacon is situated. Other methods of characterising the place, e. g., by a sequence of long and short flashes, in accordance with the Morse alphabet, or by multicolored lanterns, would not seem to be desirable. In fact, the use of the Morse signs would presuppose a perfect familiarity with the Morse alphabet, and the adoption of colored lights would be impracticable on account of the considerable reduction in luminous intensity due to the insertion of colored glasses.

The aerial beacons here illustrated are designed to emit an unlimited sequence of flashes of sufficient luminous intensity. Electric incandescent lamps or gas (e. g., acetylene or Blau gas) lanterns are used as sources of light. One of our pictures shows an electric searchlight comprising special lamps (of up to 50,000 candlepower) surrounded by a lens system which is so designed that the beams of light in clear weather are visible up to 40 kilometers as a minimum. A glass globe covers the lenses on the top, a discharge hood serving to prevent excessive heating in the interior of the lamp.

The distinctive flashes previously referred to are produced by a special switch In flashing the beacons for aerial navigation, the end signal is of great importance. While marking flashes of one and one half seconds as a maximum have been found to be absolutely sufficient, a light of about five seconds' duration is desirable for the end signal.

Wherever electrical energy is available, the use of electric searchlights will be found preferable, whereas on mountain tops and close to the seacoast, where there is no supply of electricity, gas-operated beacons are used to advantage.

Rotating beacons have also been constructed, which combine the beams of light in a bundle seen as a narrow luminous band reaching from the horizon to the zenith. In order to be seen from all points of space, this band must be given a rotation round its axis Since the whole radiation given out from the lamp is crowded into a relatively small space, the luminous intensity of rotary searchlights is much greater than that of belt-lens beacons, and may amount to many millions of candle-power.

These searchlights will not only warrant a safe flight to the airman's destination on the shortest possible way, but will prevent his crossing the frontier or the seacoast

Has the Fighting Dirigible Airship Arrived?

By Carl Dienstbach

THE veil has at last been lifted from some of the German army and navy preparations for real war in the air. It appears that the largest type of dirigible is now actually at that stage of its development in which its importance as a long range scout is well nigh equaled by its ability to fight. Far from showing its nose only where none of the dreaded armed aeroplanes are at large, its actual rôle in the battles of the future may well be expected to consist in blocking the air to aeroplanes just where free passage would be indispensable for efficient scouting.

The dirigible's comparative slowness would no more prevent it from protecting the secrets of a locality than, for instance, the comparative slowness of dreadnoughts would prevent them from protecting a sluggish fleet of transports against the torpedoes of swift destroyers.

Keeping the "inner circle" and able to perceive the approach of aeroplanes at a score of miles distance, it would need no racing speed to intercept them from any angle with a fire that has now actually been proved efficient at 2,000 yards.

"Vibration" and the lighter machine's quickened "period of oscillation" is the shibboleth that spells the superiority of the dirigible's fire. On a swaying aeroplane this has been compared with the jerking of an automobile over an ordinary road. A designer of machine guns and one-time champion revolver shot once told the writer that after having been up in both monoplanes and biplanes, only automatic pistols fired from the hand could be used to advantage This may be exaggerated, but it is the writer's own experience that in the cabin of a Zeppelin no vibration exists The slow swaying is imperceptible. The aeroplane, especially the fast light type, is essentially all engine room, and as long as its motor is turning there is vibration. Heavier machines, while less jerky in balancing, generally lose much of the advantage of speed. Machine guns have been fired from aeroplanes, but no great results are on record. Small dirigibles, with everything crowded into a car, would vibrate no less. But the results and details of tests made by the very modern war Zeppelin "Z V," on March 12th, at the Doeberitz Military Aerodrome, the first of their kind to become known, are truly remarkable. At a distance of 1,833 yards it scored a large percentage of hits with its machine gun on a target 12 by 33 feet, supported by kites. Even at 2,000 yards hits were recorded.

This was all done with a machine gun of not much greater range than a rifle's. But when Greek meets Greek in the air, when dirigible fights dirigible, larger calibers are inevitable.

It seems impossible that the history of dreadnought development should not repeat itself. In the air as on the water, the final competition will be in the size of gun that may be carried and the speed that can be made at the same time. A 30-knot dreadnought, with enormous "spotting" masts, if carrying only two extraordinarily high-powered rifles, would hardly need much armoring; it would fight at will at a range where it cannot be hit. The same principle underlies aerial fighting; all the more so because the problem, with the great vulnerability of dirigibles and the impossibility of armoring them, reduces itself plainly to hitting at a greater range, preserved by superior speed, both procured by enlarged size.

A specific complication arises from the danger of igniting the gas by the blast from larger pieces. But if care is taken to fire them only while moving at top speed, the rush of air past the muzzles positively prevents ignition by blowing away the gas. Bracing the gun-mounts against recoil offers no insurmountable difficulty, and there is no danger to the equilibrium.

No less reliable an authority than Dr. Eckener is responsible for equally startling recent revelations about the other kind of aerial marksmanship, dropping bombs to the ground, as practised by modern Zeppelins. From a safe altitude of 5,000 feet heavy bombs were dropped within circles marked by buoys on the water of the lower Elbe, of only 15 feet in diameter, showing that they could be dropped as well into the funnels of warships. Tests made on land showed that from an equal elevation a railroad station could be completely wrecked by four of these bombs. Theory has long indicated the feasibility of these performances, if necessary conditions—heavy weight of bomb, steadiness of aircraft, exact knowledge of the vertical direction, of the distance from the ground, and of the speed over the ground —are complied with. A Zeppelin furnishes all facilities for fulfilling these conditions.

The armament of a war Zeppelin actually includes one piece of heavier artillery in addition to the machine gun. The caliber seems to be little above two inches, to judge from the ranges reported, according to late reports. The target was a box 30 by 15 feet, suspended 1,000 feet above the ground from one of the military captive "kite" balloons. Near the center of both its longest surfaces there were "bull's eyes," black marks corresponding in size with the motor and the pilot of an aeroplane. From an elevation of 1,900 to 2,100 feet the "ZV," at the second trial of 15 rounds from its heavier cannon, hit both of these marks at a range of 2,100 yards, although the target was blown about like a leaf in the strong wind. While firing, the airship circled about the target. At the first trial, also with a total of 15 rounds, both the machine gun and the cannon were very efficient at a distance of 1,600 yards. In the third trial the range was increased to 2,600 yards, again only the cannon being used. The guns are both carried on a platform on top of the hull, and are removed from the proximity of escaping gas.

On March 30th the "Z V" gave a demonstration over Berlin, which puts a sinister meaning to Dr. Eckener's statements. She directly followed the "Hansa," which had traversed the city with the usual hum of the motors, but in silence. The motors of the Zeppelin of to-day are muffled as efficiently as those of the best automobiles, and it has been found that the propellers alone, at any height, escape detection. In very cloudy weather or at night the presence of a deadly airship within easy striking distance may never be suspected. No wonder that Dr. Eckener stated in the same lecture that the perfectly feasible regular airship service to British ports, to catch the "Lusitania" and considerably shorten the trip from Germany to the United States, in the absence of an adequate English air navy, was as yet out of the question for reasons of international politics.

After the new Zeppelin "Z VIII," on March 29th, ascended to 10,000 feet, even the upper air can hardly be considered a safe refuge for the aeroplane.

A protecting airship, cruising above a limited zone, needs only a minimum amount of fuel (easily renewed), and, thus lightened, climbs readily. Correct observations, difficult at best from a high altitude, are hardly helped by the excitement of being attacked, even if the aeroplane escapes destruction.

Wit and Humor Cannot Be Appreciated Without Muscular Movements

By Dr. Leonard Keene Hirshberg, A.B., M.A., M.D. (Johns Hopkins)

WALTER SHANDY, the world's greatest reasoner—he confesses it himself—was master of one of the finest chains of sublimate humor, yet for the life of him he was unable to get one line of it into the head of his wife. Mr. Strickland Gillilan says it's the simplest thing in the world to write a joke. All you have to do is sit down, strike the keys of your typewriter, and there you are. Only you must think of one first. That's where the difficulty arises.

What the subdivisions of humor may be, whether wit, fun, laughter, humor and word-play, are one and the same thing, or all different, is after all not material to an analysis of the question. To arrive truly at the fundamental element of the emotion which arises from the fifty-seven varieties of fun, known under the broad terms jest, wit, jokes, humor, fun and laughter, I selected three recent numbers of *Life*, *Puck*, and *Judge*, and submitted these to twenty individuals of average intelligence to say whether the various pictures, anecdotes, and jokes were or were not funny, and why.

One of the pictures that excited the risibilities of the subjects, was that of a little fellow who had eaten green apples. He was pictured all bent-up with his hands pressed into his little tummy. To a sympathetic mother, he said: "Mamma, I feel like a thunder-storm is inside me." Two who examined this, said: "Poor little fellow, no wonder he feels like a thunder-storm." The others all considered the incongruous rumbling of the stomach as recalling the rolling to be the crux of their interest.

The picture of a young girl sitting on a bench around whose waist were the arms of two young men, was among those shown. The legend, "A Divided Skirt," was printed beneath. One saw the humor in this with "moving eyes," as a "play upon the word *skirt*, vulgarly known as a girl, the tender element of attraction between the sexes, and the composite pleasure of discerning the hidden meaning of the word as well as the present funny vogue of that kind of wearing apparel."

While none of them overtly laughed or smiled, all admitted that the enjoyment or other emotions were accompanied with inclinations to move their facial muscles, or an imaginary movement of those muscles.

An elaborate drawing-room, with husband bending forward intently to his wife, explained this dialogue: "Wifey, will you shed any tears when I die?" The wife, a retired emotional actress, replied: "It is so long since I shed a bushel or two of them, and I am so out of practice, I cannot say," was so far from humorous to the ten women that they [illegible] as "degrading [illegible] men all considered it funny, [illegible] unmasked, because the husband [illegible]," "quibble," "sentimental" and "[illegible]."

Another illustration of five little [illegible] looking out of a window under which was the sign "Angels Rest Nursery," struck all the [illegible] as "cute," "sweet," "pretty," "pleasant," "[illegible]," and the like. They said they were inclined to smile, that is, to inhibit or reprove a tender muscular movement of the face. In a word, this picture of *Judge* was considered as in a tender key of pathos, rather than incongruity, awkwardness, or funny, false position.

A disheveled gentleman, with his cravat and collar awry, picking himself up from the bottommost step of a long flight, was shown, with this line beneath the two words, "An Optimist": "Oh, well, I was coming down, anyway."

All of the subjects maintained that this was uproariously funny, because (1) "to obscure his embarrassment, the man offered an unbelievable excuse," (2) "because he was awkward, yet unmindful of his degraded, incongruous position," (3) "there was no one around to accept a flimsy reason for his serious, yet clumsy predicament," (4) "his mechanical and unconscious position of awkwardness and impossible explanation," (5) "absurd attempt to divert attention from his inefficient faux pas," (6) "undignified and unexpected reversal of form," (7) "interruption of smooth and even tenor of one's way by an abrupt but not unhappy catastrophe." And so on. In a word, surprise, abrupt termination of smooth sailing thought, embarrassment, lame excuse, double meaning, incongruity, debasement of a neutral or unfriendly person, awkwardness, and mock reasoning were all offered as evidence of the muscular facial contortions that presented this picture as uproariously funny.

Thus it is seen that at the bottom, the stimulus that gives rise to the emotions grouped under the names of humor and pity really causes muscular movements first. These produce the mental states known as pathos, wit, and cuteness. Proof of this discovery is found in the fact that persons whose facial muscles are absolutely paralyzed cannot see a joke. Stolid-faced Englishmen, as well as persons whose cheeks and mouth-muscles are seriously burned or scarred-up, fail to see the points of definite and open jests. On the other hand, the rough, muscular, active movements of slap-stick comedy acts on the vaudeville stage are even funny to paralytics and idiots. For, the observer really laughs at such gyrations by way of his neck, head, belly, and arm muscles. In a word, the coarser the fun, the larger are the muscles that laugh. Even the man in the iron mask can enjoy a practical joke that will make a horse laugh.

The Flight of the House Fly

AT a meeting of the Cambridge Philosophical Society, Dr. E. Hindle described some experiments which he made with G. Merriman in order to determine the housefly's range of flight. During the course of the experiments about 25,000 flies were released under various conditions of weather and temperature. No less than fifty observing stations were arranged where the flies were caught in traps or on flypaper. In order to identify them they had been dusted with red or yellow chalk powder. The experiments showed that the flies winged their way either directly against the wind or obliquely to it. This phenomenon has also been observed in the case of other insects as well as of birds. The greatest distance covered by a fly was 700 meters, and a large part of this lay over open ground. In densely crowded cities, Dr. Hindle does not believe that the fly travels more than 400 meters. In order to secure the widest distribution, fine weather and warmth are necessary. Flies which were released in the afternoon, were not so widely distributed as flies which were released in the morning.

The Structure of Crystals

IN a paper before the Royal Society of London W. L. Bragg investigates the structure of some crystalline bodies, as indicated by the manner in which they diffract X-rays. For a certain number of simple crystals it is found that the interference figures may be attributed to the diffraction of a "white" radiation by a series of points situated on a configuration in space. Each of these points is a simple atom; if an atom, in a molecule, is at least twice as heavy as any one of the others, it is the configuration formed by these atoms which reveals the figure of diffraction. Two atoms of approximately the same atomic weight are nearly equal as centers of diffraction. The lightest atoms of the molecule are not grouped in the immediate neighborhood of the heavy atoms, but occupy intermediate positions. Thus, in chloride of sodium, the sodium atom has six neighboring atoms of chlorine equally near with which it can combine to form a molecule of NaCl. In some cases the atoms are arranged in a [illegible] in such a way that layers parallel to the [illegible] contain alternate atoms of each species.

Wireless Distress Signals

To the Editor of the SCIENTIFIC AMERICAN:

Newspaper reports of the false "S O S" supposed to have been sent by the "Siberia," unfortunately place this single exceptional instance in a light which, in the public mind, may offset a thousand correctly transmitted signal messages. Inasmuch as the signals S O S (s · · ·, o — — —, s · · ·) are quite dissimilar from M B S (m — —, b — · · ·, s · · ·) it seems evident that the confusion is due to the gross carelessness of the operator rather than the apparatus employed. If the signals had been H O S or I O S the excuse might have appeared more plausible, for the resemblance would have been closer.

In a pending patent the writer has proposed to prevent such serious confusion by assigning a definite tone combination which is to be used only for distress signaling, a signal which cannot be mistaken for static or other ship calls—even by a novice. The plan has been satisfactorily tested. If such a tone combination can be universally agreed upon and adopted for exclusive use in distress signaling confusion will be obviated. An ordinary seaman can tell the difference between such a distress signal and all other, where a partially trained operator may fail to pick out the present distress signal with certainty. According to this plan the distress signal will be analogous to the Klaxon horn, and its use should leave no doubt at the receiving station.

Even if this plan is not subsequently adopted the writer would suggest that the present distress signal can be made more efficient by

1. Requiring that it be sent by a musical pitch transmitter, or its equivalent, so that it can be distinguished from static X's. This means that open spark sets must be remodeled or replaced by more modern equipment.

2. Instructing all operators to give the dashes of the O full value, or more than full value (—— —— ——; not — — —), to distinguish from the dots of the two S's. A FULL space interval should also be allowed between each signal group so that the apparent running over of signals is prevented.

As matters stand, there ought to be an investigation to ascertain why the "Siberia" did not hear the false relayed radio reports and stop them. Although radio communication is far from perfect, and it should be remembered that the ordinary telegraph and telephone are imperfect, it has certainly advanced to a point where it is practical and normally reliable.

Minneapolis, Minn. PHILIP E. EDELMAN.

The Rhinoceros Beetle

To the Editor of the SCIENTIFIC AMERICAN:

Since the publication of my article concerning Dr. Friederichs' discovery of a wonderful fungus which destroys the larvæ of the well known Rhinoceros beetle, I learn from some correspondence I have had with Manila that Dr. Friederichs has himself found this identical fungus at work in the Philippines.

I quote from an official paper just received from O. W. Barrett, Esq., Chief of Division of Horticulture, Manila: "Dr. Friederichs of Apia has spent about one month here investigating cocoanut pests, and finds the same fungus (*Metarrhizium* (*Chromostylium*) *anisopliæ* (*Metsch*) *Sorokin*) is in evidence here. In fact, it is probable that this fungus has been instrumental in keeping the 'Uang' in check for many years past in the Philippines." H. J. MOORS.

Apia, Samoa.

Modern Naval Ordnance

To the Editor of the SCIENTIFIC AMERICAN:

In No. 6, vol. cx, February 7th, you mention the French 13.4-inch gun: shell, 1,433 pounds; velocity, 2,[illegible] feet. The energy by $\frac{Wv^2}{2g}$ works out equal 70,000 foot-tons, approximately. So this shell is, as you say, somewhat more powerful than our own 14-inch shell. If we take into consideration the very important factor of "ballistic coefficient," it would seem to me that the French gun shows a very considerably higher efficiency, as that factor is approximately as 8 to 7 in comparison with our 14-inch piece. This is shown by formula for ballistic coefficient: $\frac{w}{d^2}$; w = weight of the shell, d = diameter of caliber of gun. The German [illegible] gun, which you mentioned some time ago, with [illegible] of [illegible] pounds, would also look inferior to the French piece in that respect. What the weight of the [illegible] 16-inch gun's projectile is I know not; if it be [illegible] pounds, it would be just about even with the French piece.

Would you kindly discuss these matters in your esteemed publication? REV. J. H. MEYER, S. J.

New Orleans, La.

"Gore-shaped" Harbor Entrance

To the Editor of the SCIENTIFIC AMERICAN:

I am sending you a sketch of what I think is the proper way to construct an entrance to a harbor such as the ones named. I have sent copies to the Minister of Public Works, Ottawa, and to the Honorable the Secretary of the Interior, Washington. There are many harbors on your side of the lakes that are entered between piers, and I am sure a like experience must be had.

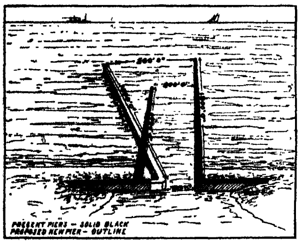
I should very much like to see a harbor entrance constructed as indicated, before I pass in my checks, as I am sure that it will work as claimed.

Owen Sound, Ontario, Canada. E. DUNN.

The letter referred to by our correspondent follows:

"*Sir:* I beg to submit to you a plan of what I think is the proper way to construct a harbor, or rather, the entrance to one, on an open beach, like Goderich or Port Stanley. Both of these harbors are entered between piers. Those of Port Stanley are about 1,000 feet long and 85 feet between them. Those of Goderich are, the south one 1,500 feet and the north one 1,000 feet long and 200 feet between them.

"Where They Fail.—Those of Port Stanley cannot be taken in a gale off the lake. When I was in the Government steamer "Petrel" I many times ran back to Long Point, 60 miles, rather than take the risk, and she was but a small vessel. In this case, however, the piers being so close together there is no sea at the harbor end; but in the case of Goderich, where the piers are 200 feet apart, a heavy sea runs right into the harbor. They have built at the harbor end what they call a check water, which does not always check. I have lain there when the sea has broken over it in a solid mass, when loading or unloading of vessels was impossible. My ideas are the result of my observations of the working of the sea in natural harbors. If you will take a chart of the Georgian Bay, and compare Owen Sound Bay with that of Colpeys, which has three islands off its mouth, you would naturally think there would be less sea at its head, under the same circumstances, than at the head of Owen Sound Bay, but such is not the case. The gore shape of the bay is the cause, it being 7 miles wide at its mouth and tapering to half a mile at the head. Colpey's Bay, on the other hand, is nearly parallel, and whatever sea passes through the gap between White Cloud and Hay Islands, rolls right to the head.



Proposed reconstruction of south pier at entrance to Goderich harbor.

"I have many times run before a storm into Owen Sound, and from the entrance to the head the sea would be quite noticeably less every mile, and at the head not half as high as the head of Colpey's Bay. Gore Bay, on the north side of the Manitoulin Island, gives the same evidence, that is, the shape of the bay kills the sea. I made a miniature harbor and entrance on the same scale as the sketch herewith, and found it worked as I expected."

The Problem of Our Navy

To the Editor of the SCIENTIFIC AMERICAN:

As an old subscriber to the SCIENTIFIC AMERICAN, I have been very greatly interested in the series of articles now being published on the "Problem of Our Navy," and especially in what you say in article IX about educating the public to view this matter in an intelligent manner.

My purpose in writing you this is to call your attention to something which, in my opinion, is doing a great deal to damage the Navy in the interior States. I am a farmer by occupation, and as such I keep several farm papers of the better class, and these are, as a rule, not hostile to Government expenditures on naval and military matters, but there are a great number of cheap farm papers being printed in this country which have a circulation of from 500,000 to 750,000 subscriptions, and about every other issue has in it some article headed "150 Million Dollars for Navy," or "Every Time Navy Fires a Shot the Value of Your Wheat Field or Flock of Chickens Goes Up in Smoke." Now, in my opinion, this is doing a great deal to injure the Navy, as most of these farmers, who comprise a large part of the voters, are living in the interior of the country. Furthermore, I know a great many of these men who read no other papers at all except some country paper which has equally warped opinions. I have just read an article in a large city newspaper headed, "Naval Efficiency," which went on to tell how prompt the Navy was in the Mexican crisis, and how it could have, to use one of their own phrases, "plowed the seas in search of any enemy in twenty-four hours," as though there was no difference between a first-class naval engagement and bombarding a more or less defenseless harbor. KARL F. JUGLER.

Black Pine, Oneida Co., Idaho.

436,682 Tons of Valueless Water Shipped With Corn Each Year

IN several particulars the systems used by United States shippers are far less economical than those employed by foreign shippers, notably in Germany. Food is started on long freight journeys in such condition that heavy freight charges must be paid on elements which have to be taken out of the food at the end of the trip before it can be used as food. One of the heaviest wasted freight items is the freight paid for the transportation of excessive moisture in corn, and in potatoes to be used for stock food or in the manufacture of starch. In Germany the culls and faulty potatoes, which in this country are thrown away, are dried so as to remove all excess water and then shipped to various points for stock feed purposes. This practice of drying potatoes for stock feed and uses in the arts has not gained great headway in this country. As a result the culls commonly are thrown away and starch is made from potatoes only when there are excess crops which make them available at a cheap price which permits of shipment to the factories. Potatoes in their natural state contain upward of 70 per cent of water which has no special nutritive value. Long shipments of potatoes, therefore, in their natural state are not practicable, whereas the Germans who have dried out the excessive water find it practicable to ship the dried product.

The waste water now being shipped in corn in the United States has a serious bearing on the actual cost of corn, and also is one explanation for the great shortage of cars at the corn shipping seasons. The American people are paying freight on 436,682 tons of water in shipping their corn from the producing sections to the market. This means that at a time when there is a great shortage of cars, there is the equivalent of over 14,556 freight cars of 60,000 pounds capacity loaded with water which is responsible for the enormous losses resulting from the deterioration of shelled corn before it is finally consumed. Figuring a car length at forty feet, this means that each year a train 582,240 feet long, or over 110 miles, not counting the locomotives, is engaged in nothing more profitable than hauling water from a few miles up to a thousand miles in the case of corn shipped to the seaboard points from the central corn producing area. Exactly how much excess freight this represents cannot be accurately determined, but as the freight rate on corn is about one cent per ton-mile, it can be seen that this hauling of useless water in corn adds materially to the cost of the product before it reaches the consumer.

Many of the big elevators in the central corn markets now have machinery for drying out excessive moisture. Comparatively few of the smaller collecting elevators have these drying machines, and the only method of drying corn possessed by most producers is storing it properly in cribs. Corn shipped during the summer months, therefore, has had a chance to dry out in the crib, but in the cold and wet months crib drying is not very effective and corn shipped during these months generally has a moisture content above No. 2 grade. Because of the moisture in such corn, few country buyers will buy corn from farmers except as No. 3 or No. 4 grade. If it grades better, the buyer, and not the producer, gets the benefit of the better rating. Under the present system the farmer has no way of determining the actual grade of his corn in his crib, and having brought it to a shipping point could not afford to return it to his bins. There is, however, a movement in communities where co-operative production is being established to inaugurate a system whereby farmers can have their corn graded at the crib and thus determine whether or not they will sell it, before they have hauled it to a shipping point. The question of moisture content and the tremendous waste in freight paid on water that is later dried out of the corn has not heretofore, according to the specialists, received the attention it deserves.

Interesting Features of Cup-defender Construction

Details of Resolute, Vanitie and Defiance

COMPLEMENTING our article and drawings of May 2nd, giving the principal features of the three cup-defending yachts, we present in this issue excellent illustrations of the "Resolute" on her first trial spin, and also some interesting details of the hull and spar construction of the yachts.

It will be noticed that each boat is framed on the system which was first originated, for yacht construction, by Herreshoff in the "Constitution" of the year 1901. As far as we know, previous to that date, reliance upon keeping the hull to shape was placed upon a large number of closely spaced, light, and shallow frames. Now the strength of any member to resist bending in the plane of its depth, others things being equal, is generally proportional to the square of its depth. It was in recognition of this law that Herreshoff, in building the "Constitution," determined to introduce a number of deep, web frames, thereby greatly increasing the stiffness of his hull without making any corresponding increase in the weight of the material used.

When "Constitution" made her appearance it was mistakenly reported that Herreshoff had abandoned transverse framing in favor of a system of longitudinal framing. As a matter of fact, he had increased the stiffness of the transverse framing, and the so-called longitudinal framing consisted of T-irons and bulb angles, introduced, respectively, along the seams of the plating and intermediately between the seams, in order to form the butt joints and to assist in holding the very light hull plating to true form. It is a distinct tribute to the constructive skill of Herreshoff that his two competitors in this season's racing have adopted the principle of construction which distinguished the "Constitution" of twelve years ago.

"RESOLUTE."—There are sixty-two frame stations in the hull of the "Resolute," and on seventeen of these there are web frames, varying in depth from 8 to 12 inches. These frames run entirely around the hull and across the deck. Intermediate between each pair of web frames are three smaller sub-frames, which are carried up well into the bilges, but not above the water line. The six strakes of plating are laid on with flush seams, the edges of the plating being riveted to nickel-steel, 4½- by 4½-inch T-irons, running along the seams, with 3-inch by 2-inch bulb angles running longitudinally midway between the seams. The covering board of the deck is of galvanized steel 7/32 of an inch thick by 18 inches wide. The balance of the deck is covered with aluminium plate 7/32 of an inch thick and 18 inches wide, the deck plates being lapped toward the covering boards. The whole deck is covered with canvas and sanded. The manganese hull plating is 5/32 of an inch in thickness, except the top strake and the garboard strake, which are 7/32 of an inch in thickness. There are six strakes of hull plating, the bottom strake overlapping the lead, to which it is very securely fastened.

Evidently, Herreshoff expects to do some experimenting with his sail plan, for he has provided two mast steps, one 33 inches abaft of the other. Judging from the photograph of the trial spin of "Resolute," it would look as though the footing of the mast was at present on the after step.

The mast, 20 inches in diameter at the foot, is built of nickel steel, stiffened longitudinally with ten 1 by 1½-inch nickel bulb angles. The foot of the topmast houses within the mainmast, footing upon a hollow steel cone riveted to the shell of the mast, as shown in our drawing. About every 10 feet of the length of the mast there is a steel diaphragm, cut away at its outer periphery to allow the bulb angles to pass through, and lightened by having holes drilled out.

"VANITIE."—An interesting drawing among those showing the construction of "Vanitie" is that of the junction of the framing with the lead. A bronze casting, to the flanges of which the frames are riveted, is attached to the lead by heavy lag-screws—an oak plank being interposed between lead and casting. Two other interesting details are those of the gammon-iron and rudder-post, each of which in a bronze casting. The gammon-iron makes a very neat finish at the stem head; it will be noted that it is recessed to receive the top strake of the plating. The rudder-post sleeve casting is also a neat piece of design. The Gardner boat has the largest centerboard of the three yachts; also, the center of gravity of the lead is lower than that of the other boats, and this, coupled with the harder bilges, would tend to give the "Vanitie" greater sail-carrying power than her competitors. The "Vanitie" has an extremely fine bow, with a very decided hollow—a feature which has marked the latest of Gardner's fast yachts. This designer has always built a very beautiful boat, and "Vanitie" will probably be the most shapely of them all.

"DEFIANCE."—The half midship section of "Defiance" shows very clearly the nature of the webbed frame construction, to which reference has been made above. Owen, her designer, more than either of the others, has cut away every ounce of superfluous material, not only in the web framing, but in every part of the construction from which it could be removed without impairing the structural strength.

The loss of longitudinal bending strength, due to the adoption of a wooden skin in the place of bronze plating, is compensated in the Owen boat by making the seams of the inner and outer skins of wooden sheathing break joints, as shown in one of our drawings. We noted in our previous article that the inner skin of fir is fastened to the framing by bronze bolts, one of which is shown herewith in a *separate sketch*. Attention also is drawn to the bronze screws which pass through the inner skin from the inside and take hold of the 1½-inch outside mahogany skin. The hull will be painted with white enamel paint below the waterline and above the waterline the mahogany will be highly varnished. An interesting detail is the turning up between the transverse frames of the edges of the diagonal strapping of the hull, in order to gain additional stiffness.

The mast construction is generally similar to that of the "Resolute," with the difference that there are six bulb angles of deeper section running the length of the mast in place of the ten shallower bulbs used in the mast of the "Resolute."

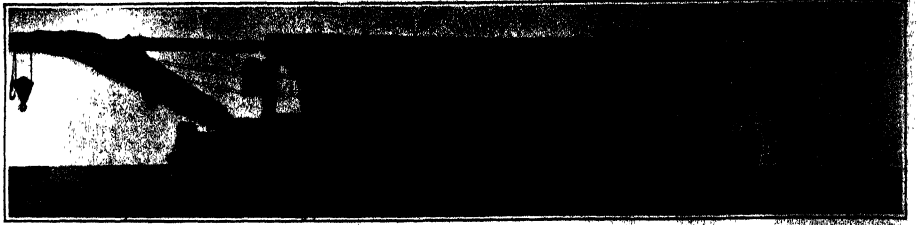
Some interesting details of cup defender construction.



Powerful, electric wrecking crane designed for the underground clearances and conditions of the Grand Central Terminal.

A 100-ton Tunnel Crane

A DOUBLE-END electric wrecking crane with independent hundred-ton capacity cranes at each end, has been received, recently, by the New York Central Railroad for use in case of accidents or wrecks within the electric division of the road. The crane is especially designed for the underground clearances and conditions existing in the Grand Central Terminal, although it may be used also on the main line of the electric division. The machine will be dispatched at high speed under its own power to the scene of the accident.

To design a crane of the large capacity required, under the unusual limitations imposed by the conditions of tunnel operation, was not a simple matter. At the express level head-room for raising the boom and room at the side for slewing were both restricted. Also excessive concentration of wheel loads had to be avoided. The crane had to be designed to perform wrecking operations that are quite different from those found elsewhere.

The procedure in case of a wreck underground will be somewhat as follows: If possible, the wreckage would be lifted clear of the track, and the crane would then back out with it. If, on account of lack of head-room or because of the size of the piece, it could not be raised off the track, one end would be lifted with the main hoist, and with the auxiliary hoist a special truck would be placed under it. The crane would then drag away the load.

The car body of the crane is 67 feet long with a wheel base of 51 feet, and it is carried on two compound trucks made up of two four-wheel trucks each. A cradle on which the car body rests allows the compound trucks as well as each single truck to have perfect freedom to swing when making turns. There is a comprehensive system of air-operated telescopic outriggers or jack-beams to aid stability during heavy lifting, and to distribute the load over a greater area. The independent cranes at each end of the car have a structural mast and boom, accurately turned roller path and rollers, and slewing mechanism. All of the motions of operation may be performed independently, and with loads up to the capacities of the motors may be performed simultaneously. All the clutches are operated pneumatically to insure quick and sure engagement and release. Four 200 horse-power motors are used for propelling the machine, and two of 150 horse-power each for hoisting and for operating machinery. The propelling motors are controlled from each end of the car, and all four may be used for traveling, or, if desired, only the two at either end. They are capable of operating safely on fluctuations of line voltage between 300 and 750 volts, direct current. For intermittent and emergency service, as might be required with the third rail out of commission, or when suitable cable connections could not be made with the feed line, there is installed on the crane a high-capacity storage battery, consisting of 230 cells. It has a capacity of 75 amperes for 8 hours with a maximum discharge rate of 350 amperes for 2 hours.

On a formal test, conducted by the railroad officials, the crane propelled itself at the rate of 34 miles per hour while hauling an 80-ton rolling load. On solid foundation with outriggers, the cranes showed a capacity of 100 tons with a 24-foot 2-inch radius straight ahead, or 6 feet 6 inches to either side of the center. The same capacity was shown with a 22-foot radius operating at 12 feet either side of the center, and with a 13-foot 8-inch radius swinging 180 degrees. Without outriggers the capacity was 50 tons and 25 tons with a 13-foot 8-inch radius swinging 180 degrees. The crane was designed and built by the Industrial Works from specifications prepared by the New York Central Railroad.

The Iceberg Patrol

EVER since the "Titanic" disaster travelers have looked with new respect upon those ancient ice monsters that come down out of the North each year, on their final voyage to the torrid South. Instead of eagerly hoping that an iceberg will be sighted, their presence is looked upon with apprehension. During the iceberg season the North Atlantic is patrolled by United States revenue cutters in the endeavor to locate icebergs. The accompanying photograph shows two huge icebergs and the United States revenue cutter "Seneca," which has just discovered them. The find was made on Easter Sunday. The icebergs were moving southward rapidly into the path of ocean steamers. A warning was immediately sent out by wireless telegraphy to all ocean steamers in the vicinity. The larger one of the icebergs rises to a height of over 125 feet above the water, making the "Seneca" appear like a mere pygmy in comparison. The Government is using every precaution to avert another "Titanic" disaster.

Fire Protection on Ocean Liners

By Dr. Alfred Gradenwitz

THE increasing development of ocean navigation has resulted in attempts, on the part of engineers, not only to improve the technical appointments of steamships and to augment the comfort of passengers, but to provide as efficient a protection as possible against any risk of accident. At the recent London Conference, representatives of all the leading nations agreed upon the most appropriate measures to be taken in this connection. On account, however, of the unprecedented dimensions of the "Imperator" and "Vaterland," the latest additions to their fleet of ocean liners, the Hamburg-American Line, in the case of these mammoth vessels, decided to go far beyond the rules laid down at this Conference, adopting not only an improved and admirably comprehensive system of water-tight bulkheads, but a novel type of fire-protection apparatus.

It will be readily understood that a floating palace, accommodating a population of over 5,000, should require far more efficacious measures of precaution than the average liner of relatively modest dimensions, the more so, as any accident there may assume the proportions of a real catastrophe. This is why the two vessels in question have been equipped not only in accordance with the best practice in connection with the fireproofing of buildings, but with many new and unique arrangements.

All iron walls of the passenger decks have been lined on both sides with a fireproof cement coating, cast on wire gauze or molded in slabs. Comprehensive tests made in a special building at the Central Headquarters of the Kiel Fire Brigade, have brought out the excellent qualities of walls and doors such as these. Any bulkhead openings traversed by the passenger corridors on the various decks have

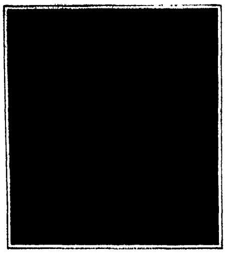
Have Plants an Unknown Sense?

Some Curious Instances Which Seem to Indicate That the Tendrils and Roots of Plants Have a Mysterious Power of Feeling Objects at a Distance

By S. Leonard Bastin



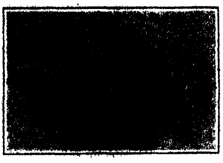
The plant leaned over and secured a hold with its tendril.

IN his pursuit of knowledge the man of science is continually coming across matters which it is difficult, if not impossible, to explain. One of the most sensational facts that have recently come to light is the discovery that plants appear to possess a special sense. It is too early to hint at an explanation of the happenings which force us to this conclusion, but we now know that plants are able to feel objects at a distance. That is to say, they act as if they were aware of the presence of a certain thing, even though they may not be in contact at all. It may be of interest to give a few of the most startling cases which have come under notice.

Everybody knows that the sundew catches flies. The leaves of this plant are, of course, covered with tentacles which, being very sensitive, close in round the captive. But the foliage of the sundew has another remarkable characteristic. If a fly is fixed about half an inch from any of the leaves a most astonishing thing happens. After a short interval it is seen that the sundew leaf has moved perceptibly toward its victim. Soon the cruel tentacles have actually reached the unhappy fly and are seen to be slowly moving round their prey. There is now no chance of escape, and with every moment the fate of the insect becomes more certain. A few feeble wriggles and the fly is dead. When one comes to think of it, it is very strange that a plant should be able to go in pursuit of its prey in the manner indicated. Some plants are very unscrupulous; unable to secure a living on their own account, they prey upon the more hard-working of their fellows. Such is the dodder, a most virulent parasite, which, apart from the first few weeks of its existence, has no roots or leaves and exists as a blood sucker on other plants. The seed of the dodder germinates in the soil, and from this arises a curious thread-like growth. Now it is of vital importance that the young dodder should be able to seize hold of some suitable host, such as a clover plant, for instance. It is strange to watch the manner in which this thread-like growth works in and out through the grass stalks seeking for a victim. When it comes within a certain distance of a clover plant the dodder grows forward at a very rapid pace until a hold is secured. Even the sturdiest plant must go down before the attacks of the cruel parasite. The thread-like shoot is, within a few weeks, multiplied by the thousand, and from every point are produced suckers which draw away the life-giving sap.

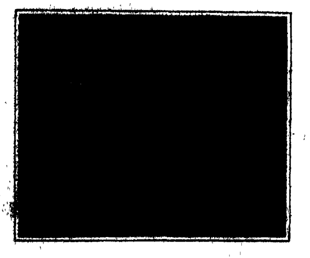
In much the same way the tendrils of climbing plants show quite clearly that they can feel things at a distance. A sweet pea plant which was used in an experiment proved to be exceptionally clever in this respect. A stick was placed near the plant at a distance of two inches, and during the few hours which followed a very strange thing happened. The tendril, which at first was held between the leaflets, where it had been developed, dropped down to a horizontal position. This was, of course, merely a matter of growth, but it was almost at once followed by a very decided movement of the tendril toward the stick. Finally, the whole of the upper shoot of the plant leaned over, meanwhile the tip of the tendril was busy making sure of its hold. One could not very well get away from the idea that the tendril knew, if the word is permissible, that a support was within reach.

Darwin once said that in their clever ways the root tips of plants seemed to evidence as much intelligence as was to be seen in the lower animals. The following instances show that the great scientist was stating the case very mildly.



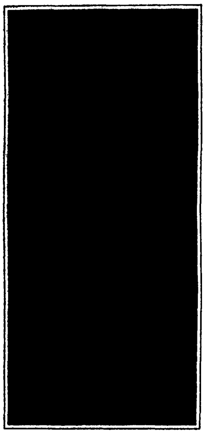
Fly set up before a sundew leaf.

Reaching the fly with its tentacles.



The fern sent down a root on the outside of the pot down to the water in the saucer.

How the hazel roots went down through the willow.



The trailing cactus sent down its roots through a hole in the roof.

Sometimes plants find themselves in very awkward situations. Such was the fate of a hazel bush, the seed of which had been placed in the upper part of an old willow tree. Now there was a certain amount of soil, formed of decayed leaves, where the seed of the hazel tree started, and for a time this was sufficient for the needs of the bush. But as the plant increased in size the need for more root room became imperative. Yet the hazel tree was a full 12 feet above the ground. Now a strange thing happened, for the hazel bush started to send out roots to the soil beneath. These traveled downward through the hollow trunk of the willow, and finally reached the ground. When this occurred the hazel bush at the top of the tree started to flourish with renewed vigor, and at the moment of writing threatens to become more prosperous than its host. Another strange case of a plant growing down to soil many feet beneath comes from South Africa. This was a species of the trailing cactus which was rambling over the roof of a shed. The roof was formed of galvanised iron, and at one point rust had eaten its way right through. As soon as the stems of the cactus reached this point it at once started to send down an immense quantity of roots through the hole to the ground beneath, a distance of 9 feet. We may take it that the plant was not satisfied with its existing accommodation, and the soil in the shed (which happened to be nice soft mold) offered a tempting medium for fresh root activity. But how on earth could the plant know that it would reach the ground at the end of the journey through the air?

A few years ago some plants of the tropical creeper known as *monstera* were established in a greenhouse. These plants are very fond of rambling about the roofs of the structure in which they are growing, and will often send down roots to the ground. In this particular case the plants made no attempt to develop their aerial roots until they were over a large water tank. Then the roots were produced in abundance, and these traveled down through the atmosphere and finally reached their goal many feet beneath. In another case a little fern sought out some water with an intelligence that seems to be almost uncanny. The plant was growing in a pot, which was kept standing in a saucer; the latter was always well filled with water. Now one may suppose that the fern did not have a sufficient supply of water to meet its needs in the ordinary way, and it determined to get into touch with that in which the pot was standing. Accordingly, the plant sent down a special root, on the *outside* of the pot to the water in the saucer.

In conclusion it is interesting to call to mind a very striking case of root intelligence which was observed by that celebrated botanist, Dr. Carpenter. The instance has never been explained, and it may perhaps be a good plan to give the original description, which was published in 1860. It is as follows: "In a little hollow on the top of the shell of an old oak (the outer layers of which, however, and the branches are still vegetating) the seed of a wild service tree was accidentally sown. It grew there for some time, supported, as it would appear, in the mold formed by the decay of the trunk on which it had sprouted; but this being insufficient, it has sent down a large bundle of roots to the ground, within the shell of the oak. These roots have now increased so much in size, that as they do not sub-divide until they nearly reach the ground, they look like so many small trunks. In the soil, however, toward which they directed themselves, there was a large stone, about a foot square, and, had their direction remained unchanged they would have grown down upon this. But about half a yard above the ground they divide, part going to one side, and part to the other; and one of them branches into a fork, of which one leg accompanies one bundle, and one the other; so that on reaching the ground, they inclose the stone between them, and penetrate on the two sides of it."

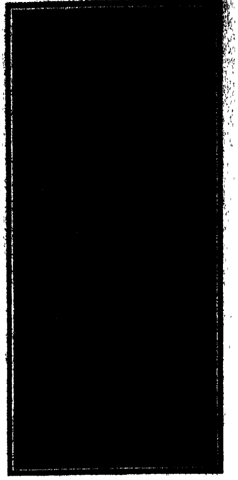
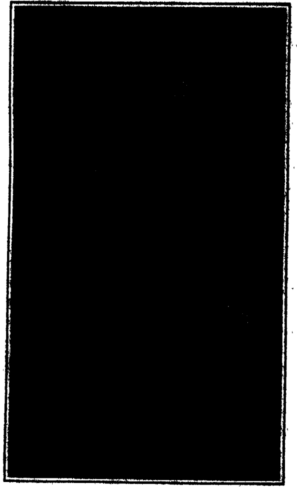
How the "strain" insulators are used.

Insulators buried in snow at the Great Falls power plant, Butte, Montana.



Example of "suspension" insulation.

Subjecting a chain of suspension insulators to a break-down test.

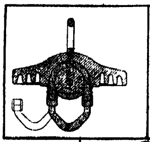


Flow of sparks around the skirts of two insulators; the top disk is punctured.

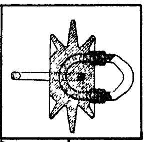
Evolution of the High-tension Insulator

LESS than a quarter of a century ago the first alternating current power transmission line was erected in the United States. The current was transmitted at 3,000 volts, which was considered very high pressure in those days. With that beginning the development of high-tension transmission lines progressed steadily, until by the end of the century, 60,000 volts had been reached. Then, for a time, there was a halt. A serious obstacle was encountered. The development of generating and transforming machinery had outgrown the development of insulation and the former had to wait for the latter to catch up When a new system of insulation was discovered, high tension took up the march again and there was steady progress, until, now, we have transmission lines of 150,000 volts and consider 250,000 volts not an impossibility, but a probability in the course of the next few years

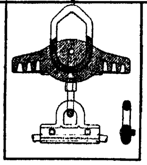
The making of an insulator may seem a very simple thing, involving merely the quantity of insulating material placed between the conductor and the support That was the first idea, but it was soon found that insulators exposed to the weather accumulated impurities, dust and the like, so that when they became wet, they offered a path—more or less imperfect, but nevertheless a path—for leakage of electricity. Then more attention was paid to the shape of the insulator. It was formed with a number of petticoats so as to increase the under surface on which dust and rain would not be liable to collect. With increase of voltage the insulators became larger and larger and the petticoats more numerous until finally they became so cumbersome as to present serious mechanical difficulties in their construction and in the maintenance of the poles upon which they were mounted.



Section of suspension insulator.



Section of strain insulator.



Suspension insulator and line clamp.

The use of higher voltages also developed other weaknesses. Glass was found too brittle and liable to break with variation of temperature. Furthermore, it was easily wetted, so that in rainy weather a film of water would form upon it. Porcelain was substituted for glass and found better in many particulars, but its chief insulating quality lies in the surface glaze. When this is cracked—and it is liable to be cracked by action of the weather—moisture entering the cracks will expand when frozen and rupture the insulator, resulting in a short circuit. Unfortunately when a high-tension line is short circuited, surging is set up which is liable to rupture other insulators along the line. The effect is cumulative, so that serious damage may result from one defective insulator. A search was made for better insulating material, and a number of compounds have been discovered which show greater mechanical strength, which are unaffected by temperature changes and which, being of an oily nature, are not readily wetted with water; that is, the water collects in drops rather than in a film over their surface.

But the problem was more than one of material only. It was a mechanical problem. The pin type of insulator had been outgrown. The next development was to suspend the insulator from the cross arm, instead of supporting it on a pin. Because a flexible support can be made much lighter than a rigid one, this reduced the weight on the cross arm at once. The conducting wire could be supported at a greater distance from the cross arm than was possible before. Furthermore, a chain of insulators could be used in place of a single, large, rigid insulator. This is the type of insulation now in common use on high-tension lines, the only objection being that the line is apt to sway in the wind and might come in contact with its support. This may be prevented by proper spacing and the use of lateral guy lines also made up of chains of insulators known as "strain" insulators. Still another method is to "dead end" the conductor at each pole by means of "strain" insulators, using short loops to carry the current past the cross arm. Both the "suspension" and the "strain" types of insulators consist of disks formed with petticoats or flanges and furnished with hooks at each side, to permit of connecting any number together in a series long enough to provide the desired insulation. The series is often "graded" from a large insulator at the conductor to a small one at the support, thus reducing weight and at the same time increasing the insulating qualities of the series.

The accompanying detail drawings illustrate the degree of perfection to which the present-day insulators have been developed. The constructions are the invention of Mr. Louis Steinberger, one of the pioneers in

THE ELECTRICAL INDUSTRY AND THE YOUNG MAN

What Electricity Might Do for Him—What He Might Do for Electricity—A Little Article about His Work in Life

By JAMES H. COLLINS

One day, not long ago, a party of officials from Germany visited the main plant of the Westinghouse Electric & Manufacturing Company, at East Pittsburgh.

They walked down an aisle that seemed a mile long, past countless machines where the operators, a number of whom were girls, were winding insulated wire. They were solid serious Germans—real well-fattened husbands of the German *Hausfrau's* ideal. It was a long walk. The most serious member of the party plodded along without comment until the end of the aisle was reached. Then he turned to the guide and said:

"This is a big building."

They were taken around a corner and conducted back through another aisle of the same length, full of men and girls and machinery, and again the serious visitor said nothing until the other end was reached. Then he declared:

"This is the biggest building I ever saw!"

Still the tour continued. They turned another corner, and walked down a third aisle, and now the serious German was getting winded. When the end was reached, he mopped his brow and exclaimed, in astonished conviction:

"Ach! This must be the biggest building in the world!"

Now, suppose a young fellow with his career all before him—say, a liberal arts sophomore, or high school senior—went through the same plant.

He, too, would be impressed chiefly by the size of the place, and very properly. For it is an immense works full of technical apparatus and processes. It is said to be the largest machine shop in the world. Nor is this all of Westinghouse, because the company has plants in other cities of the United States, and in Europe.

A young student would get the general impression that, if he were employed by Westinghouse, he would be connected with a very large concern indeed, with its thousands of workers, and millions of feet of floor space, and plants and output distributed all over the globe—surely a job to be proud of.

Still he might not see the path of opportunity open to him in the electrical industry.

The electrical business has been called the most forward-looking of our great industries. Every day more things happen in electricity than in any other line. More new devices are developed, more progress is made, and electrical service and products touch humanity more intimately.

The path is there, but it needs to be pointed out.

There was a time, certainly, when primitive man's whole idea of the application of power to work lay in carrying his few possessions around with him. And here begins the path of electrical opportunity. He lugged things around until it occurred to him to make pack animals carry them, and that led to the development of the drag or sled.

It was a great day when he cut his sled runners out of the trunk of the tree instead of from a limb. They turned round then instead of sliding, and much friction was eliminated.

For then the wheel was evolved, and civilization ever since has been pretty largely a matter of wheels—wheels and ways to turn them.

At first it was human muscle at the potter's wheel, and wind or water at the mill wheel, and horses on the chariot. These were the sources of power for centuries, and as long as they were retained the wheel that was turned never got very far from the power that turned it.

By and by, however, steam was utilized to turn wheels, and then came power transmission. Wheels could be hitched to wheels by shafts, gears, belts. One big wheel turned by a steam engine ran hundreds of lesser wheels, animating a whole factory.

Yet even with steam and the mechanical transmission of power, wheels were never made to turn each other at any considerable distance from the prime mover. It is true that cableways with wire ropes running on pulleys supported on piers were successful for distances of several miles—the cable street car was familiar only yesterday. It is true, also, that hydraulic and pneumatic transmission of power were in a very promising state of development yesterday, and are even utilized to-day under certain conditions.

But, suddenly, something happened to all the mechanical methods of power transmission.

Electricity came in between the big wheel at the prime mover and the little wheels at the other end, and the face of material civilization was changed almost in a day.

The superiority and wonder of electricity lie in its ability to turn wheels in ways never dreamed of with any mechanical system. It is the ideal and universal form of power transmission.

A copper wire is stretched from the place where power is generated to where it is wanted for work. Old limitations of [illegible] are [illegible] disregarded. There [illegible]. The wire can go up heights, down depths, around any maze of corners, and to distances that are restricted only by questions of economical operation. At one end of the wire the dynamo moves. And at the other end these mysterious waves that we call "electricity" turn a wheel in a motor—the power is available.

Besides turning wheels, electricity can be taken off the wire as light or heat, so it has a three-fold application.

Electricity is the most *flexible* form in which power can be had.

It may be generated in enormous quantities at the central station, by steam or water, and delivered in the tiniest driblets to anybody who wishes to purchase.

Without electricity, there could be no power in the average home.

But with electric current from a central station miles away, any home may have cheap power in any quantity. A penny's worth may be bought to sweep a room or chop the hash. Or it may be utilized as heat to iron the towels, or as light wherever needed. Electricity is available instantly, at any hour of the day or night, calls for no skilled attendant, is under perfect control, clean, safe, cheap, and delivers just enough power for the task.

This flexibility, economy, ease of control and cleanliness is just as great in the largest applications of industrial power—machines directly driven by electric motor make the modern factory cleaner, quieter, lighter, more efficient and better in every way.

⁂

The ambitious young man, leaving school and becoming part of the Westinghouse organization, would start at the very beginning of the path of electrical opportunity. But with energy and ambition he could soon travel far enough to see that it branched off in two directions.

First, there is the technical end of the business, engaged in developing and improving electrical apparatus.

Second, the distributing end, which is busy applying electricity to a wider and wider range of human service.

⁂

As the visitor walks through the Westinghouse works, he sees a bewildering variety of operations. Metal is being molded, forged, welded, bored, turned, pressed, spun, ground, polished. Wire is being wound in an infinity of ways, and sheets and plates of conducting metal built up to complicated patterns. There is a range from the gigantic to the microscopic, for in one plant big cranes handle parts for enormous turbo-generators, and in another the bearings of wattmeters are being fitted with tiny jewels. There is constant talk of armatures, commutators, condensers, resistances, alternators, rectifiers, single-phase, polyphase—a perfect Babel of technical terms.

In the end, however, it all comes down to about the same thing.

No matter what the contraption is called, or how large it may be, or how delicate, or complicated, it is likely to be just a special device for conducting current along a particular path so that it is made to accomplish a particular form of work.

Electrical development has been largely the development of ingenious paths for current. This development of new paths has been going on since Franklin provided his kite-string path for the lightning. Each year brings new subtilties, and every important new electrical installation calls for special refinements. So, the young man who finds the technical side of Westinghouse activities to his liking will have plenty of room to turn around in, and unlimited scope for the future.

Take the electric light, for instance. It began with the arc lamp. Close upon the arc lamp followed the incandescent bulb, in which current had to pass through a charcoal filament in a vacuum. Then followed improvements on the charcoal filament. Then the carbon was metallized—better yet. Then *metal* filaments of tungsten and tantalum were devised—and improvement after improvement on the metal filament. Better, and still better.

To-day the electrical industry is agog over the latest invention in incandescents—the metal filament in a bulb filled with nitrogen vapor, which gives out a glorious sunburst of several thousand candle-power, with a quality closely approximating daylight.

Another example is found in alternating current—peculiarly a Westinghouse development.

The first commercial electricity was direct current. That is, it flowed continuously from the generator in one direction along the wires. Direct current was extremely limited in scope, because it could be transmitted only a few miles. Its voltage, or pressure, was low—only 100 to 200 volts. So it had to be sent over heavy copper cables—in effect, a lazy flow in large volume, and not equal to much work after it had traveled any considerable distance. Even had direct current been effective on long transmission, the cost of the cables was a barrier against its practical development.

Alternating current, on the contrary, is divided into infinitesimal halves as it issues from the generator, each alternate half flowing in an opposite direction, with anywhere from a few to many thousands of alternations per second.

It can be sent at high voltage through small wires to great distances—at present practical transmission has reached a radius of 200 miles. Its pressure can be "boosted" up at any point along the line to maintain or accelerate the flow, and when the current arrives at the point where it is to be transformed into work its pressure can be "stepped down" to any required voltage.

The Westinghouse organization took up alternating current in its babyhood, when it was largely a scientific curiosity from Europe, neglected because nobody believed it could be made practical, and even regarded as dangerous.

First, a generator producing alternating current up to 1,000 volts, and capable of transmitting electricity to a distance of a mile or more, was built by the Westinghouse organization.

But how to use it for light and power was another matter, because such high pressure instantly destroyed any form of electric lamp, was unsafe inside a building, and would not turn the direct-current motors then in use.

The "transformer" of Gaulard and Gibbs, at that time a laboratory freak from Europe, was taken up by the Westinghouse organization, and perfected, so that current at 1,000 volts could be transmitted over considerable distances, and then reduced to normal lighting pressure. The first great installation of alternating current for lighting was made at the Chicago World's Fair in 1893, and was distinctly a Westinghouse triumph. To day, transformers are made in all sizes, for all voltages and types of service, up to 150,000-volt giants for transmission lines.

And with the high-voltage transformer comes the condenser terminal, perfected by Westinghouse to lead high voltage currents safely into the transformer, and capable of handling over 150,000 volts and tested for 375,000 volts.

Motors, too, are paths devised to make electricity perform many sorts of work, from the little fractional horse-power motor that turns a dentist's drill up to the 156-ton Westinghouse electric locomotives used by the Pennsylvania Railroad. And to the making of new types there is no end.

The mercury rectifier is another path for current, and a mighty interesting one. It is a large glass bulb, filled with mercury vapor, and in use looks just like the familiar Cooper Hewitt lamp used for lighting. It gives the same greenish-bluish light—and is, in fact, a modification of that lamp. The mercury rectifier takes an alternating current at two poles, splits the two halves, and sends them out, flowing in the same direction, at a third pole, and thus converts alternating current into the direct current necessary to charge the storage batteries of an electric automobile.

The little electric flatiron now coming into such wide use for housework is a particular path for electric current, its heating element being designed to transform electricity into heat with the highest economy. So are the other heating devices for household use, such as the electric stove, electric radiator, electric toaster, coffee percolator, chafing dish and so forth.

So are the industrial heating devices found in every manufacturing plant—the soldering irons, melting pots, welding devices, vulcanizers, sterilizers, heaters and many other conveniences for operation by electric current. So are the electric meters, the spark coils and vibrators, the controllers and converters, and almost every other form of electrical apparatus—paths—all paths.

⁂

The other great division of the Westinghouse organization is that which distributes this infinitely varied product to the world.

Not long ago, an engineer, visiting East Pittsburgh, found that Westinghouse electric generators aggregating half a million horse-power were under construction, and he further learned that the average monthly output of the Westinghouse Electric Company approximates one-half million horse-power.

In 1890, census returns showed that the electrical energy used in our factories amounted to less than sixteen thousand horse-power. To-day, the aggregate is fully five million horse-power.

In 1890, our street railways used a few hundred thousand horse-power of electrical energy. To-day, their total exceeds five million horse-power.

In 1890, the central station industry was a struggling infant. To-day, it is employing capital aggregating two and a half billion dollars, and one of the best banking authorities in the United States says it can normally develop at the rate of four hundred million dollars yearly for the next five years.

Figures of this sort could be strung out to any extent. A few big items are given here to indicate the scope of the market for electrical products, and to make clear to the young man who might find the distributing part of the Westinghouse organization most to his liking, what a field lies open to him.

From the days when alternating current was being developed by the Westinghouse organization, this "wholesale" side of the demand has been fascinating to the kind of young man who likes the human and the technical blended in his work.

From one industry after another has come up problem after problem, to be solved by study of the conditions and original designing of apparatus. And the Westinghouse organization has not waited for the problems to come, but has gone out into many industries and dug them up on its own initiative.

Special generating, transmission and motor equipment have been made to solve these problems, both in alternating and direct current apparatus.

Twenty years ago the 1,000-horse-power Westinghouse generators built for the Chicago World's Fair were regarded as giants. But to-day, single generating units of 45,000 horse-power are being built by the Westinghouse Company for central station and electric railway service, and promise to become quite common by reason of their great economy in producing power. It is largely a matter of developing the market for such quantities of power—for a single generator of that capacity would run all the men's clothing factories in the United States.

In steel mills, motors have been adapted to the individual driving of every machine, and made fireproof to withstand the hard service.

In mine and other service, they have been made water-proof.

In the textile industry, they have been modified in many ways to meet peculiar demands in spinning and weaving.

In railway service, they have been built to give high speeds and great tractive power, coupled with maximum strength and minimum weight.

In machine building, printing, shoemaking, construction and many other industries they are provided in every conceivable size and type, for individual or group driving of machinery, making possible the purchase of power at the most reasonable prices, its use with the least loss, the utmost convenience in running at any hour of the day or night, and ease of measuring power consumption of individual machines or departments.

And every day this wholesale demand for electrical apparatus grows, not only in volume, but in breadth and interest.

As an illustration of that, the enormous field in transportation may be touched upon.

The electrification of our railroads is pretty certain to come about during the present generation. Electrification of suburban divisions running out of the largest cities has demonstrated the immense economy of the new power, and this is being followed up by the electrification of mountain divisions where present operating costs are high. Water power is being developed on such a scale as to provide electricity for railroads everywhere. Trolley systems are being linked up into true railroad systems Electric power is proving to be the most economical means for developing new territory, giving service to communities beyond the economic reach of steam roads. Electrification of the steam roads is no longer a technical matter, but one of finance and management. Even in water transportation, the electrical propulsion of ships promises to be the most economical means of utilizing the high speeds and low costs of steam turbines.

On top of this there is an enormous "retail" demand—and the still more enormous untouched retail field, which must be turned into consumers for the vast amount of current that will be produced by the great electric power plants now just coming into operation and still building.

To market such volumes of power, electricity must be extended not only to factories, but to homes. To put electricity into the homes calls for the highest type of educational selling. Apparatus is being perfected daily by the manufacturing end of the electrical business. The electric flatiron, washing machine, heating and cooling devices and so forth are ready for the public. Electricity is beyond question the ultimate solution of the servant problem.

The carbon filament lamp was standard yesterday. Originally, it consumed so much current that it was restricted to well-to-do homes. Then its efficiency was increased, and it came in reach of a wider public. To-day, the new nitrogen lamp is cutting current consumption down to as little as one-twelfth the consumption of the old carbon filament lamp, and the use of electric light has been made universal, in theory—with the practice delayed only a little. Small household motors have been perfected in the same way. Likewise household heating devices—and electric cooking for many homes is a possibility of the immediate future.

In 1880, the country's whole output of electrical apparatus was worth only two and a half million dollars. In 1890, it had grown to only twenty millions. To-day, a million dollars' worth of electrical apparatus is produced every day in the year.

Each development of apparatus, each lowering of costs, extends the field for putting electricity into more homes, in theory.

But, as a practical proposition, people must be taught and persuaded. They must be shown how to use those electrical conveniences which are already within their means, and how a larger capital investment in apparatus will secure lower cost of living and greater comfort.

So the popularization of electricity calls for the highest kind of selling effort. Along with the potential home demand, which increases far more rapidly than selling effort can keep pace with it, there is the small industrial demand from manufacturers, merchants and business concerns whose requirements of a few motors and electrical tools do not bring them into the wholesale class.

To cultivate this vast retail field is not the work of the central station alone, though the latter, it is true, sells the current. It calls for the close co-operation of the electrical manufacturer, and is a field in which the Westinghouse organization has always been active, making studies, developing sales methods and working with the distributors and users of electricity.

If all the demand from homes and small industrial concerns were suddenly to cease, there would still be a lifetime of work for hundreds of young men in taking care of the new retail demand just rising—that for electricity on the farm. This is coming, surely and quickly, with the electrification of the railroads, the development of water-powers and the extension of central station transmission systems into country districts.

Now, what can the electrical industry do for the young man?

And what can he do for the electrical industry?

It is usually assumed that a business so largely technical needs none but engineers, electricians and men of technical training.

But that is a very narrow view—quite mistaken.

To-day, industry is being humanized, both in its relations with the public and with its own workers. New standards are being set and new ideals worked out—ideals that would have been scouted as theoretical and altruistic five years ago.

The electrical industry always needs the young man of general education, broad sympathies, clean life, energy, ambition, open-mindedness, the faculty for getting on with other men, the ability to look ahead and visualize to-morrow, the man who can teach and inspire others while he learns and grows himself.

Electricity's need for young men is constant, in every department of the industry, both production and distribution.

Knowledge is an advantage, whether technical or general, and at the same time is only something to start from.

The young man himself is chiefly a potentiality, to be introduced into the industry somewhere, given specific tasks, tried, gauged, placed, developed and advanced according to his individual ability. If he has the energy and the ambition, the path of electrical opportunity is open to him. If he is not well placed at one kind of work, he can be tried at others—the field is unlimited in its scope and diversity. If he can grow, his development will mean the development of the industry in some detail or direction, and no matter how fast he may be capable of advancing, there is certain to be plenty of room ahead of him, always.

Electricity is essentially a young man's business.

It is alive all over, both in ideas and in its physical organization.

It is a business of to-day and to-morrow—not yesterday.

Business in general is very apt to be grounded on personal policy. The opinions and methods and energy of a few leaders prevail. Time and change bring habit and tradition. Conservatism creeps in, narrowing the outlook and limiting the possibilities.

But the electrical industry is grounded on scientific truth. It grows on a solid basis of experiment and research. Being built on actualities, and always subject to correction of natural laws, there is no room for the entrance of personal rule, prejudices, habits, traditions, the limitations of mere opinion.

As a young man's business it is typified in the Westinghouse organization. From the first, Westinghouse has been an organization of young men, alive, looking into to-morrow, trained down to the minute. It is a young man's organization to-day, and always will be in spirit and methods, no matter what its age may happen to be in years.—*Advertisement.*

PATENTS FOR SALE

A VALUABLE APPLICATION for a tide motor has just been allowed. This invention will prove revolutionary in the generation of power and will tend to make up for the exhaustion of Nature's own resources by the utilization of one of Nature's own forces. It is adapted as a tide and stream motor. It will prove especially useful for the generation of electricity Fullest possible information will be given by writing to the undersigned, George F. Lemmon, 1773 East 12th Street, Cleveland, Ohio.

SCIENTIFIC APPARATUS

GLASS APPARATUS, thermometers for scientific and industrial laboratories, surgical glassware, experimental work For further particulars address Laboratory Supply Co., 128 State St., Rochester N.Y.

SITUATION WANTED

WANTED—by a young man 25 years of age, position at outside work. Has good education and is very capable. Has the best of references. Address American, Box 773, New York City.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., INC.

Inquiry No. 9357. Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather.

Inquiry No. 9359 Wanted the name and address of a firm that makes razor blades for all makes of safety razors.

Inquiry No. 9360. Wanted the name and address of parties making pipe fittings such as ferrules, stems and bowls such as could be used in the making up of calabash pipes for smoking.

Inquiry No. 9361. Wanted to buy a Nut Cracking Machine, especially good for Pecans.

Inquiry No. 9362 Wanted the name and address of the makers of a machine for splicing ties.

Inquiry No. 9363. Wanted the names and addresses of manufacturers of machinery for printing on intaglio copper plates.

Inquiry No. 9364. Wanted the name and address of buyer of mica in a crude state.

Inquiry No. 9365. Wanted the name and address of a manufacturer of machinery for embossing tin foil as is used in packing cigarettes.

Inquiry No. 9366. Wanted the name and address of a manufacturer of wire wheels, front axles complete with steering or separate, light steel pressed bodies, fuel tanks with cocks, pressed steel frames, mufflers, motors of the two-cylinder opposed type, cushions and many smaller parts for cycle cars.

Inquiry No. 9367. Wanted the name and address of a manufacturer of an automatic [illegible] machine.

Inquiry No. 9368. Wanted, the name and address of glass-bottle manufacturers or glass blowers who can manufacture a glass bottle and perforate it with some 12 small holes, in large quantities for export, to sell at a popular price.

Inquiry No. 9369. Wanted, the names and addresses of users of Indian Steatite (Soapstone), Corundum and other Indian minerals, in quantities.

INVENTOR'S SUPPLIES

[illegible]

Analyzing the Human Singing Voice

(Concluded from page [illegible])

partial tone (fundamental and overtones) separately and all of them collectively," observes Dr. Muckey. "The first thing we notice is that the waves vary in length, the wave in the lowest line of the voice-tone photograph being longer than that in any other line, and the one in the second line being just half of that in the first. We find that the tone represented by the second line is the octave of that represented in the first line.

"The waves gradually diminish in length as we go up in the series and the pitch of the tone rises. This proves that the length of the wave determines the pitch of the tone. Then we observe that the waves vary in height, the waves in the first line being highest. They gradually diminish in height as we go up in the series.

"Our experiments have demonstrated that the fundamental tone, or the one with the highest wave, has the greatest carrying-power, and that the other waves, representing the overtones, diminish in direct proportion to the lessening of the height. Thus we have intensity and carrying-power equal to the height of the wave.

"Our experiments have shown, also, that any change in the number and relative intensities of the partial tones makes a corresponding change in the quality of the tone, and, so, we have quality dependent absolutely upon the number and relative intensities of the partial tones. If we take away one partial tone it changes the quality of the tone as a whole, and if we take away several it makes a very decided change in the quality. Similarly, if we change the intensity of any one or more of the partial tones, it makes a corresponding change in the quality."

He adds, in summing up the results of his two decades of labor with Prof. Hallock:

"Resonance has been the keynote of our work. It has been at once our tool, and the object wherefor we have striven. For our purpose resonance may be defined as the reinforcement of a tone by a quantity of more or less confined air, the inherent rate of vibration of which is identical with that of the tone reinforced. Such a quantity of air receiving successive impulses from the vibrating source, or object, comes into vibration itself, thus giving to the surrounding air a much greater amplitude of vibration and consequently greater intensity and carrying-power to the tone."

Several improvements in the manometric flame tone analyser have been devised by Prof. Hallock. A simpler construction and the elimination of much of the rubber tubing of the Koenig-Helmholz apparatus have brought it to a stage where it not only registers more satisfactorily the tone-production of the voice, but begins to fulfill the long-felt want of a recorder of the tonal quality of musical instruments of every character, and especially of those of the string family—the pianoforte, the violin, the 'cello, etc.

Fire Protection for Ocean Liners

(Concluded from page 416.)

been closed, in accordance with the best actual practice, by fireproof glass doors designed to withstand a temperature of upward of 1,000 degrees.

In addition to the iron bulkheads thus lined with fireproof coatings, a new type of fire-resisting transverse walls has been fitted at regular intervals, the design of which is another outcome of the above tests. These walls are likewise provided with fireproof doors. Special care has been bestowed on the insulation of the staircases. The main staircase, over which passes most of the passenger traffic, has an entirely fireproof lining, so that each vestibule constitutes, as it were, a smoke-proof lock. Fireproof elegant glass doors insure an easy access to the staircases. This scheme, which complies with the very stringent regulations of the German police authorities for the fireproofing of department stores, warrants, according to any human provision, a narrow localization of any conflagration and a safe escape from [illegible]

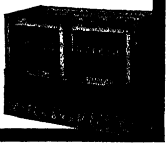
SAFETY SERVICE AND SPEED

in your car, because it produces the best results from your motor and preserves its life and serviceability.

HAVOLINE Oil is refined from *one uniform base*, the lubricating fraction of which is *admittedly superior* to that of other crude oils. This assures you the same high quality and perfect lubricating value regardless of where or when you purchase—the standard being thus *basically* protected.

Our "special process" of manufacture exempts HAVOLINE entirely from the detrimental effects of destructive distillation. The potency of the oil is retained, giving you the highest lubricating value yet the least carbon deposit.

Therefore HAVOLINE prevents frictional losses and insures thorough motor efficiency.

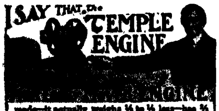


Buy only the oil in the Blue Can. Two 5 gal. cans to the case.

Tell us your make and we'll tell you your grade.

Ask your garageman or write to us direct for testimonials of HAVOLINE users who own your make of car

INDIAN REFINING CO., Dept. K, New York



I SAY THAT the TEMPLE ENGINE

made—it actually weighs ⅓ to ½ less—has ⅔ less bulk—occupies ⅓ to ½ less space—than any horizontal engine of same power capacity. Look at the "Temple" Design and see for yourself that it is true. Made 2 H. P. to 50 H. P., using gasoline, kerosene, alcohol and distillate.

Why, then, pay out good money for a big, heavy, unwieldy engine, and then "blow in" some more money for a big special truck to carry it, when you can easily put the light, compact "TEMPLE" on anything having wheels or on skids, planks, or stone boat, that one horse can haul anywhere. It can even be put on a push cart and pulled about by one man.

It's the "TEMPLE'S" (Inverted Vertical Cylinder) Design that accounts for its unequalled portability—its quiet, smooth running—its delivery of full rated power, whether MOUNTED, or STATIONARY—its small fuel consumption—its low upkeep cost—its durability, long life, etc. All this means that

The "Temple Pays for Itself"

many times over, by its clear saving of ⅓ to ½ the fuel consumed in other engine designs—to say nothing of the "TEMPLE'S" many other more serviceable and more economical features.

You may doubt my claims for the "TEMPLE'S" vastly superior all around accomplishments in farm and contracting service, but you can't doubt the facts and figures I can submit to prove them. Just a penny now for a (postcard) brings you these facts and figures, also information about engines you simply can't get from any other source, and which may be worth hundreds of dollars to you later on. Do it now.

TEMPLE MFG. CO.

2300 54th Ave., Cicero, Ill.

ROTARY PUMPS AND ENGINES

Their Origin and Development

An important series of papers giving a historical resume of the rotary pump and engine from 1588 and illustrated with clear drawings showing the construction of various forms of pumps and engines. 38 illustrations. Contained in Supplements 1109, 1110, 1111. Price 10 cents each. For sale by Munn & Co., Inc., and all newsdealers.

America's Telephones Lead the World
Service Best—Cost Lowest

from London "Daily Mail"
from "Electrical Industries" (London)
Why is
Continent

From "Le Petit Phare de Nantes," Paris

"But today I found I had to talk with Saint-Malo, and, wishing to be put through quickly, I had my name inscribed on the waiting list first thing in the morning; the operator told me—though very amiably, I must confess—that I would have to wait thirteen hours and ten minutes (you are reading it right) in order to be put through."

Herr Haberland, Deputy, in the Reichstag

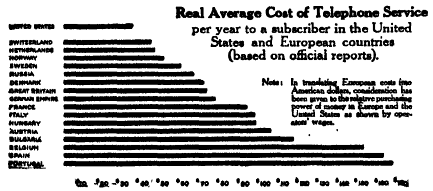
"The average time required to get a connection with Berlin is now 1½ hours. Our business life and trade suffer considerably on account of this lack of telephone facilities, which exists not only between Dusseldorf and Berlin and between Berlin and the West, but also between other towns, such as Strassburg, Antwerp, etc."

Herr Wendel, in the German Diet.

"I refer here to Freiberg. There the entire telephone service is interrupted at 9 o'clock p. m. Five minutes after 9 o'clock it is impossible to obtain a telephone connection."

Dr. R. Luther, in the Dresdner Anzeiger

"In the year 1913, 36 years after the discovery of the electro-magnetic telephone, in the age of the beginning of wireless telegraphy, one of the largest cities of Germany, Dresden, with half a million inhabitants, is without adequate telephone facilities."



Real Average Cost of Telephone Service per year to a subscriber in the United States and European countries (based on official reports).

Note: In translating European costs into American dollars, consideration has been given to the relative purchasing power of money in Europe and the United States as shown by operators' wages.

These are the reasons why there are twelve times as many telephones for each hundred persons in the United States as in Europe.

Represented in Great Britain by Markt & Co., Ltd., 6 City Road, Finsbury Sq., London, E.C.; France, by Markt & Co., Ltd., [illegible]; Germany, [illegible] by Ludw. Loewe & Co., [illegible]

In the rear part of the promenade deck, there is a guard-house and central station for all fire alarms. Five professional superintendents, trained at the Kiel Fire Brigade, under the guidance of a responsible chief officer, have been intrusted with a well-organized watching and patrolling service and with the upkeep of all fire alarms and signaling apparatus on board. There are in all 450 fire alarms converging toward an annunciator board in the guard room. These electrical fire alarms, which are arranged to work automatically at a given temperature, are installed not only in the cabins and saloons, but, with wise foresight, in the less frequently used holds, refrigerating chambers, post offices and storage rooms.

As regards the rooms destined for the crew, another step was taken to insure even greater safety against fire, by the installation of automatic sprinklers. There are 800 sprinklers of this kind aboard the "Imperator." As soon as some of them are actuated automatically, the pressure in the pipes decreases, thus operating an electrical alarm at the central station. The extinguisher pipes are in their turn connected directly with the general sea-water conduits, thus providing always the water required to produce the necessary head and dispensing with any special pump in the event of an outbreak.

Reference should also be made to the Rich apparatus, arranged to work with carbonic acid instead of with steam as heretofore, and to the new Draeger apparatus, both of which, it will be recalled, won the SCIENTIFIC AMERICAN Safety Medal. These, in conjunction with the customary König smoke helmets, are bound to prove most helpful in the case of smoke production.

Evolution of the High-tension Insulator

(*Concluded from page 418.*)

the development of high-tension insulation, he being the first to make successfully, and on a commercial basis, high-potential insulators from a material other than glass or porcelain. It will be observed that the suspension members are imbedded in the insulator and interlaced, so that should the insulating material be shattered, the line would still be supported by a chain made up of the suspension members. Owing to the swivel form of the terminal, two or more units may be connected or disconnected in the fraction of a minute, no special tool being required to operate the connecting nut, as a plain wrench, a nail or even a piece of wire may be employed. The clamp, which is shown suspended from one of the insulators, is formed with flared ends to prevent crystallization and possible breaking of the conductor as it is swung back and forth by the wind. The disk or suspended type of insulator has become so standardized that it is used on all lines operating above 50,000 volts, and even on lines of 44,000 volts in some instances. The 10-inch disk "strain" and "suspension" insulators here illustrated have been tested to show a puncture value in oil of 150,000 volts, and of 100,000 volts when tested to dry arc value. The rain arc value is 55,000 volts, line voltage 25,000 volts and mechanical value 20,000 pounds, while the weight is not 11 pounds.

A New German Life-saving Costume was exhibited at the International Conference on the Safety of Life at Sea, in London, by its inventor, Paul Raschke, a tailor of Breslau. It is made of a composition of aluminium and rubber, with a padded belt around the body under the arms. The outfit includes a pouch intended to contain supplies of food and drink. The inventor demonstrated his apparatus in the Thames. He adjusted the suit in less than three minutes, jumped in the river, where the costume kept him afloat, and propelled himself in any desired direction with a pair of paddles. Taking a cigar from his pouch, he lighted it and smoked most of the time he remained in the water, about 45 minutes. He claimed that the suit kept him comfortably warm in the cold water.

Why are Delco Equipped Cars So Eagerly Sought After by Intelligent Automobile Buyers?

Why is it that before the end of the season Delco Equipped Cars are almost invariably oversold?

Why is it that Delco factories in spite of their constantly increasing output have never been able to supply the demand made upon them?

Frankly—it is because more than 115,000 car owners have so emphatically demonstrated Delco efficiency—

Because—owing to the fundamentally correct principles upon which Delco engineering is based, the owner of a Delco Equipped Car is practically certain of perfect cranking, lighting and ignition no matter whether he drives his car sixty miles an hour with few stops or fifteen miles an hour with many stops.

There are three underlying principles of successful electrical equipment for a gas car—

First—Its ability to maintain a fully charged battery, no matter how fast or how slow the car is driven.

Second—Its ability to stand up under the excessive strains and stresses of hard driving.

Third—Its adaptability to the particular car upon which it is used.

The simplicity and correctness of Delco design—the almost unbreakable character of Delco construction and the wide range of Delco efficiency have back of them the testimony of three years of actual service on the very highest type of American cars, and the experience of more than 115,000 thoroughly satisfied owners.

That is why this season as in former seasons, the demand for Delco Equipped cars is greater than the factories can supply.

Improved kinematograph target apparatus used in England to train sharpshooters.

Training Marksmen by the Kinematograph

FOR some years past considerable ingenuity has been expended in the effort to turn the kinematograph to distinct value in the training of marksmen. Unfortunately the problem was attended with many peculiar difficulties, that of accurately and instantaneously recording a hit upon the moving subject being the most elusive. In order to render the application of any pronounced value, both to the recruit and to the officer in charge, it is imperative that the hit shall be shown upon the screen.

Recently such a system has been perfected in England, and has met with warm approval from military experts. Briefly, the system comprises the projection of pictures upon a moving screen, which is perforated by the bullets, the hit being revealed by a light showing through the puncture, and the picture being held stationary for a few moments to enable the full results of the hit to be observed.

While the apparatus is necessarily somewhat intricate, its operation is extremely simple and automatic throughout. The projector follows the usual lines with a few special attachments to adapt it to this application. The screen is of special design, and is formed of traveling rolls of paper, the movement of which is controlled by the lantern mechanism.

The essential feature of the invention is a very sensitive microphone, which is connected to a delicate relay. The microphone itself is set up above the screen out of the firing line. When a shot is fired the report of the discharge is caught by the microphone and brings the relay into operation. This relay controls a magnetic clutch placed upon the motor drive of the projector, and, at the sound of the shot, this clutch is brought into operation, the drive is interrupted, and a powerful instantaneous brake applied to arrest the movement of the projector, with the result that the image of the film at which the marksman fired upon the screen stops in the gate, producing the same steady stationary image as if it were a lantern slide. The blades, or opaque sectors, of the revolving shutter are mounted in a free wheel manner, so that although the projector mechanism [illegible] the blades continue to revolve at normal speed. Consequently, although the picture is stationary upon the screen the light is intermittently cut off as in ordinary kinematography.

While the microphone and relay are essential parts of the invention the screen moving mechanism is in every way as important. The screen itself is carried upon the face of a large iron box, the back wall of which forms an impenetrable obstacle to the bullets. The front space of the front wall of this chamber is filled entirely by the screen. At the bottom is a roller on which the paper is coiled. The free end of the paper is then carried upward to the top of the space, where it is passed over a second roller, and down once more to be wound upon a second bottom roller, mounted above the first one. Consequently, as the paper is fed upward and round the top roller it descends to the third roller to be coiled up, and as the movement of these two lower rollers is identical and synchronous the tension of the paper is maintained. In this way two traveling thicknesses of paper are provided, the foremost moving upward and the one behind moving downward. The movement, however, is not continuous, but intermittent, and is governed by the mechanism acting in conjunction with the microphone and relay.

But in addition to the foregoing two thicknesses of vertically moving paper there is a third sheet. This is coiled at one side upon a vertical roller, passed across the screen space behind the two above-mentioned thicknesses of paper and wound upon a second vertical roller at the opposite side. This sheet is employed to serve as a stiffener to the two thicknesses in front, and is kept very taut. It also reduces the possibility of showing a repeat hit. The sheet is moved by hand at various intervals, according to the extent to which the target is used. In some instances movement of an inch or two in a horizontal direction once an hour is quite adequate. It will thus be seen that the screen in reality comprises three thicknesses of paper superimposed vertically, two of which travel in a vertical direction, while the third moves in a horizontal line.

Behind the screen, within the steel chamber, but out of the firing line, powerful electric arc or incandescent lamps are fitted. Thus the interior of the chamber is brilliantly lighted, but this fact is not apparent from the front because the paper screen forms an opaque wall.

When the shot is fired it penetrates the three thicknesses of paper, and the light placed behind showing through the puncture indicates exactly where the bullet has struck As the picture at this juncture is stationary upon the screen, it is possible to determine at once from the position of the shot-hole relative to the subject of the picture whether the shot was effective or otherwise. For instance, if the picture represents a sharpshooter firing from behind cover, the officer can ascertain immediately whether his man at the firing line hit his opponent, and if such were done before the latter fired.

The duration of the period for which the picture stands stationary is governed from a control board, which is automatic in its action. The relay connected to the microphone is mounted at its base. At the extreme top are coils serving as magnetic blowouts to quench the induction spark of the screen-shifting mechanism, which is a solenoid automatically operated from this point. Immediately below are timing solenoids and a dash pot and plunger. As soon as the projector mechanism is arrested, and the picture is brought to a standstill upon the screen, this plunger commences to move. When it has reached the limit of its travel it re-establishes contacts, which sets the screen mechanism in operation. By varying the travel of this plunger the stationary period of the picture upon the screen may be varied within certain limits, according to circumstances.

The screen mechanism is very simple. On the horizontal roller upon which the paper is coiled to be unwound is a ratchet and pawl movement actuated by a solenoid. When the plunger on the control board reestablishes contact the ratchet of this screen roller is moved, and the outer sheet of paper moves upward for a distance of one eighth of an inch, the return or second sheet moving a corresponding distance downward simultaneously. As the two sheets are displaced in opposite directions the shot-hole in each, through which the back

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Energy from the Sun

IN view of the fact that the sun delivers energy to the earth at the rate of 7,000 horse-power per acre, it is not surprising that the problem of devising a motor which shall transmit this energy into useful work has proved an attractive one to the experimentalist, as a study of the files of the SCIENTIFIC AMERICAN during the past few years will show. Thus, in California there was erected a plant in which the heat rays were made to converge upon a steam boiler, that generated sufficient steam to run an 8-horse-power pump—this plant being an elaboration of Ericsson's early experiments upon which he is credited with having spent $150,000. Two more modern and perhaps better-known installations are those erected at Philadelphia, and later at Meadi, Egypt, the plants in these two experiments being designed on the principle of concentrating the sun's rays upon a boiler of large area and very low pressure.

An analysis of the Egyptian plant, made by Mr. A. S. E. Ackermann, B.Sc., in a paper read recently before the Society of Engineers in London, shows that, while these experiments have decided scientific interest, they give but little promise of the commercial success of the sun motor. The temperature of the sun is estimated to be about 6,000 deg. Cent., and, theoretically, about 95 per cent of this should be convertible into work. The energy convertible into mechanical work falls from 95 per cent of 7,000 horse-power per acre to 25 per cent, or say, 1,750 horse-power per acre. Even this amount cannot by any means be realised in practice. In some regions the atmosphere cuts it down by nearly fifty per cent, though the loss is considerably less in arid areas.

Recently Mr. Ackermann made a series of trials at the Meadi plant which extended over three weeks; during which he was able to record as the highest output only 19.1 pump horse-power from a sunshine-absorbing plant covering seven-eighths of an acre. That is to say, he recorded less than 20 pump horse-power, as against the 6,000 horse-power which would have been obtained from a perfect motor, capable of utilizing the sun's radiation direct. In the Philadelphia plant, in a test lasting for five hours, Mr. Ackermann obtained results equivalent to the development of an average of 18.54 horse-power from a sunshine-absorber of 0.41 acre extent. The maximum development in the test was 26.8 horse-power and the lowest 8.6 brake horse-power.

These results show how little promise there is of obtaining mechanical energy from the sunshine on a commercially economical scale. Such plants as these at Philadelphia and in Egypt suffer, in an exaggerated form, from the drawbacks attaching to wind power, namely, the great area occupied, the costly cumbersomeness of the plant, and the great variability in the rate of power production. A windmill 40 feet in diameter has an output of about 8 horse-power, and costs $250 per horse-power; and it can be relied upon to work not more than one third of the total number of hours in the year.

In the Meadi plant the five steam generators consist each of a huge mirror 201 feet long by 14 feet in width, which concentrates the rays on a cast-iron boiler, 3½ inches by 14⅝ inches by 205 feet long. The mirrors are mounted on rollers and follow the sun from east to west The plant gives the best results when working with a steam pressure of 6½ pounds gage. In the Meadi test the engines did not work well, and the steam consumption was very high. But even with low-pressure turbines the output in brake horse-power would amount to an average of only 70 brake horse-power per acre This means that a 1,000-kilowatt plant would call for a gathering ground of nearly 14 acres, and even this would be available at the above rates for not more than about three thousand hours per year under very favorable climatic conditions.

Of course there would be a great increase in the output, if the steam pressure were raised, say, to 200 pounds per square inch; but since a sun motor must be placed in the open air, the increased losses due to convection would greatly offset any gain due to the higher pressure.

Construction of Battleships at Government Yards

THE question of the wisdom of constructing battleships at Government yards once more has been the subject of debate in the House of Representatives, when the arguments in favor of the policy were strongly urged by Representative Fitzgerald of New York. For many years the SCIENTIFIC AMERICAN has advocated the policy of having at least one battleship under construction at one or other of the navy yards; and the arguments which we advanced many years ago when the subject was first under discussion are valid to-day.

The country has at least one yard, that at New York, which is fully equipped for building dreadnoughts of the largest size. In fact, the keel has just been laid of a ship which is to-day the largest under construction for any navy. There have been successively built at this yard, during the past twelve years, the "Connecticut," the "Florida," and the "New York." The work on each ship was absolutely first-class, and in the case of each there was an increase in the rapidity of construction over its predecessors.

The principal arguments in favor of Government construction are, first, that a spirit of healthy rivalry is promoted between the Government and the private shipbuilding yards, and, secondly, that the construction of a battleship serves to keep together a large navy yard working force, which, if there were no such work on hand, would have to be more or less broken up and scattered during the slack season. As to the first condition, it is sufficient to refer to the facts brought out by Mr. Fitzgerald that, when the Government yards were first utilized for the construction of battleships, contractors took from 36 to 40 months in excess of the contract time in which to complete them; whereas to-day vessels authorized for the Navy, because of the keen competition of the Government yards, are completed within the time fixed by contract.

The advantages of maintaining a large working force of skilled mechanics, continually, at such a yard as New York is self-evident. Now that so many of the minor repairs are done aboard ship, there is not sufficient overhaul work at the yards to keep the force up to its full quota. That the private establishments understand full well the economic value of holding together a thoroughly drilled force of workmen is proved by the fact that they will often, in slack times, take work at cost or very little above cost merely for the sake of holding their forces together and keeping their plant in operation.

There is the further and very forcible argument that in the event of hostilities, when the yards have to be suddenly worked to their fullest capacity, the existence of a large body of trained and well co-ordinated forces would be of inestimable value.

Col. Roosevelt's Discoveries in South America

DURING the last two or three years the northern drainage slope of the Amazon basin has been much more fruitful than the southern of geographical discoveries, including the notable achievements of Hamilton Rice, Koch, and Farabee It is therefore a matter of special interest that the Brazilian expedition of the American Museum of Natural History, led by Colonel Roosevelt, has traversed a long stretch of virgin territory among the southern tributaries of the great river, and made important additions to the map in the very heart of the region which most contemporary cartographers mark "Unexplored." Colonel Roosevelt was accompanied by the experienced naturalists George K. Cherrie and Leo E. Miller, of the American Museum, his son Kermit, and [illegible] sion headed by Colonel Rondon, [illegible] well known in connection with [illegible] interior of Brazil.

That the results of this expedition [illegible] tremely valuable is sufficiently attested by [illegible] the explorers collected over 2,180 birds and [illegible] besides a number of reptiles, [illegible] mainly in regions not previously visited by [illegible] The principal geographical achievement of the expedition is claimed to have been the mapping of a river nearly a thousand miles long, the existence of which had previously been only vaguely known or suspected, and which on account of its problematical character, had acquired the name Duvida ("Doubt") The Colonel's description of this stream is as follows:

"The upper part of its course was utterly unknown to anybody except the wild Indians along its banks, while the lower part was known to a few rubber men only. The river takes its rise in the high uplands of the western part of the state of Matto Grosso, just north of the thirteenth parallel of south latitude, and between longitude 59 and 60 west of Greenwich.

"We embarked in latitude 12 degrees 1 minute south and longitude 60 degrees 15 minutes west.

"The river ran with many doublings and twistings, almost due north into the River Madeira, where its entrance was at about 5 degrees 30 minutes south latitude.

"In latitude 10 degrees 58 minutes south we struck the mouth of a big affluent flowing from the right and in latitude 9 degrees 49 minutes south we came to the mouth of another affluent flowing from the left.

"The Duvida River in point of volume is like the Rhone, the Elbe, or the Hudson, but is too much broken up by rapids to be navigable except in the lower parts. In about 7 degrees 30 minutes south latitude it joins another river, practically the same size, flowing from the right.

"From about 11 degrees 48 minutes to 10 degrees 48 minutes south latitude the course of the Duvida is almost an unbroken series of rapids, there being no clear day's run without rapids."

Though not questioning Roosevelt's good faith, several geographers have expressed doubts as to the accuracy of the statements above quoted. The Madeira River, of which the Duvida is said to be a tributary, is not only well known, but regularly navigated by steamers far above the point where the Roosevelt party claims to have entered it from the newly found river. How could this great tributary have hitherto remained unknown to the many people who travel up and down the Madeira? An unnamed explorer whose views are quoted at length in the English press suggests that the Colonel may have sailed down the Tapajos, while Sir Clements Markham is inclined to think that he descended the Canuma, the greater part of which has never been explored. In either case, as he undoubtedly entered the Amazon by way of the Madeira, he must have reached the latter by some unknown cross-channel, or, according to one suggestion, by way of a temporarily flooded lowland. The journey was made at the close of the rainy season, when, as is well known, South American rivers indulge in curious freaks.

The best maps of the Amazon region, such as Mello's "Atlas do Brazil," the large Olavo Freire map, and the great German atlases of Stieler, Andree, etc., throw little light on this question; in fact, a comparison of these maps with one another shows unmistakably that the cartography of the whole region where the Duvida is supposed to run is, at present, merely conjectural. The reported starting-point of the canoe journey corresponds closely with a supposed upper portion or branch of the Jamary, a tributary of the Madeira, and the relief of the country in this immediate vicinity negatives the probability of the explorers having entered the drainage system of the Tapajos. It is, however, by no means certain that the river shown at this point (on most maps by dotted lines) is really connected with the Jamary. It may well be the Duvida. Following the alleged course of the latter northward we find only one cartographic feature inconsistent with its existence, viz., the Rio Machado, which if correctly shown on the maps, would intersect it at right angles. Here, again, however, we have to do with a river whose course is largely a matter of rumor and conjecture.

What at first sight appears to be a serious objection to the explorer's claims, viz., that so important a tributary of the Madeira would have been well known long ago to navigators of the latter river—is easily disposed of by reference to Roosevelt's description of the Duvida. A river broken by innumerable rapids and exceedingly difficult to navigate even in a canoe might well have remained unexplored [illegible] Most of the streams entering the Madeira from the right are shown on the best maps by dotted lines, except at their immediate junctions with the main river; and one of these is, in all probability, the [illegible]

We believe that the Roosevelt [illegible] a notable addition to the map of [illegible]

[illegible]

[illegible].—Unostentatiously and [illegible], the world's trade through the Panama Canal is shortly to be inaugurated by the passage of a mail steamer of about 5,000 tons from the Pacific to the Atlantic. The clearing of the [illegible] slide has proceeded sufficiently far to allow of the passage of a ship of this size. The opening was hastened forward by the congestion of freight due to the closing of the [illegible] Railway.

Barges for the New York State Canal.—The New York State Barge Canal will have a capacity to pass barges of 2,000 net tons. The dimensions of the barges will be: Length, 270 feet; beam, 35 feet; and draft, 12 feet. The total lift through locks of the Barge Canal is 16 times that of the Panama Canal, and it has 10 times the number of dams, 14 times as many locks, and 20 times as many structures. The cost, as far as construction and engineering is concerned, will be within the estimated cost—a fact for which full credit should be given.

A Fatal Omission.—One of the greatest needs of the Navy just now is the large drydock which is under construction at Pearl Harbor, Hawaiian Islands. During the recent debate on the Navy Bill in the House, however, the "little navy" men succeeded in casting out the provision for this dock, on a point of order. This makes it impossible for the contractors or the Navy Department to complete the construction of this most important work. Apart from the urgent need for the dock, it is a fact that unless the provision is put back in the bill in the Senate, the Government probably stands to lose all the money it has expended on this improvement.

Zoelly Turbine Installation.—The recently constructed electric station for the city of Paris in the suburbs at St. Ouen, employs among others two steam turbine groups designed by the Société Alsacienne. These turbines are connected to alternators on the same shaft. Of the Zoelly type, the present turbine develops 15,000 horsepower and operates at 1,250 revolutions per minute. By the automatic working of a by-pass, it is able to develop 50 per cent above the normal for a short time. The Zoelly wheel works on the impact principle, and the present design allows of adopting periphery speeds which are relatively high. Wheel disks are forged in a single piece with the hub, and the blades are dovetailed around the edge of the disk.

The Most Powerful Locomotive.—What is probably the largest sudden increase in the size of locomotives has taken place in a new freight locomotive, built by the Baldwin Works to serve as a pusher over heavy grades on the Erie Railway. The engine is of the Mallet articulated type; but its weight and power have been greatly increased by adding a third pair of cylinders and a set of six-coupled driving wheels, which are carried by the frame of the tender. The boiler has 6,886 square feet of heating surface, and the steam is utilized in one pair of high pressure cylinders and two pairs of low pressure cylinders, all of which are of 36 inches diameter by 32 inches stroke. The working pressure is 210 pounds to the square inch, and the drawbar pull is 80 tons. The total weight is 477½ tons, of which 376½ are upon the drivers.

The Location of the Alaska Railway.—Now that the Government has decided to build the Alaska Railway, one of the first questions to be determined will be that of the selection of the engineer to lay out the best location for the road. The locating of a new line is the most important work that the engineering staff of a new railroad have to do. The locating engineer is a specialist. Upon his good judgment depends the question as to whether the completed road is to cost so many million dollars more or less; and in the selection of the man for this work, political considerations should have no weight whatever. If the Government wishes to show how well it can lay out, construct and equip a railroad, it should select its staff entirely upon their merits, that is to say, upon the work which they have done under conditions approaching those which will be met with in Alaska.

Combined Rack and Adhesion Locomotives.—The railroad line running between Usui and Toge is obliged to run upon very heavy gradients when on the mountain, the difference of level being some 1,760 feet over a length of but 7 miles. On this portion there was used a rack-rail system of the Abt design and some 20 locomotives specially employed for the mountain stretch, ordinary locomotives being used on the other parts of the railroad. Lately the steam locomotives were replaced by electric locomotives of the Allgemeine type, designed to run on 600 volts continuous current with third rail. The locomotives are designed on the combined adherence and rack-rail system, and are said to be the most powerful rack-rail electric locomotives yet built. The electric motors are mounted on the car floor, and drive a counter-shaft by gearing, whence a driving bar system operates the wheels. The rack wheels are driven by a separate [illegible].

Science

Water-Proofing Concrete.—The United States Army Engineers have long used the following mixture in waterproofing cement: One part cement, two parts sand, three quarters pound of dry powdered alum to each cubic foot of sand. Mix dry and add water in which has been dissolved three quarters pound of soap to each gallon. This is nearly as strong as ordinary cement, and is quite impervious to water besides preventing efflorescence. For a wash, a mixture of one pound of lye and two pounds alum in two gallons of water is often used.

Teak Forests in Java cover 1,480,000 acres, and, as the area reafforested is two and a half times as large as the area felled in a given time, this magnificent stock of timber is continually increasing. A pest of the Java teak plantations is alang grass (*Imperata arundinacea*). In order to prevent the incursions of this plant, as hoeing is too expensive, the foresters sow a leguminous plant, *Leucena glauca*, between the rows of teak seedlings. This chokes the alang, keeps the soil clean, and enriches the soil in humus and nitrogen, and ultimately disappears with the increase of the forest cover.

Some High Ocean Waves.—Regarding the greatest height of waves reported by different observers, Lieut. Raffi of the "Jules Henry," recently noticed waves of 66 feet in the Atlantic. But this does not appear to be the highest on record. In 1863 Admiral Fitz-Roy affirmed in his "Weather Book" to have seen waves of 60 feet. Capt. Kiddle of the "Celtic" observed 70 feet height, and the same figure is also reported by the commanding officer of the "Narrung" in the region of the English Channel during the tempest of last winter which prevailed on the Channel and the North Sea. It is not stated how the observers estimated the height of the waves, so that some latitude must be given on this account.

Metals at Absolute Zero.—Prof. Dien has recently published some interesting observations on the behavior of metals at the absolute zero of temperature. The infinite electrical conductivity of metals at absolute zero, which has been rendered very probable by the work of Kamerlingh Onnes, is explained if we assume that the distribution of molecules at the lowest temperatures is perfectly regular, so that the displacement of electrons along certain lines encounters no resistance. By increasing the temperature, the molecules are set in a state of thermal agitation and the free path of the electrons is reduced; whence the electric conductivity is reduced also. It appears probable that temperature variation affects only the mean free path and not the number of electrons nor their mean velocity.

Increasing the Yield of Gasoline from Petroleum by Use of Catalytic Nickel.—An English company is securing a very large yield of gasoline from petroleum by catalytic hydrogenation. The method is practically the same as that recently applied in the conversion of liquid fats to a solid form or to solid fatty acids with a higher value. A tall still with a conical bottom receives a steady feed of petroleum and hydrogen gas under pressure. This mixture enters at the bottom and passes over finely divided nickel which catalytically brings about a reaction between the hydrogen and oil. Gasoline is formed which passes off as a vapor at the temperature of the still, while the heavier hydrocarbons formed fall back into the catalyst and react with hydrogen. Finally a tarry residue must be removed and the nickel regenerated. The issuing gases pass into a cooling chamber where the gasoline is condensed. The hydrogen unused up to that point is forced back and passed through the still once more. The efficiency of the process is very high.

The Colors of Odoriferous Plants.—Messrs. Schubler and Koehler have published the results of some very interesting observations they have undertaken on the relations between the colors and odors of various flowers. They have analyzed more than 4,200 plants, and they find that: (1) white is the most common color for flowers, and (2) that red, yellow and blue are more general than violet, green, orange and brown. The different odoriferous species divide themselves among the different colors in the following manner:

Color of Flowers.	Number of Species Examined.	Number of Species Having Odors
White.........	1,194	187
Red.........	933	84
Yellow.........	950	77
Blue.........	594	31
Violet.........	308	13
Green.........	153	24
Orange.........	50	3
Brown.........	18	1
Total.....	4,200	420

As will be seen, the number of plants possessing odors is only one tenth the total number of species. We also see that in proportion, it is among the white flowers and then the red that we meet the greatest number of odorous plants.

Aeronautics

A New Aeroplane Stabilizer.—W. E. Verclaire, of Chicago, Ill., in a patent, No. 1,093,746, provides for tilting the planes in which the propellers rotate to agree with the tilting of the stabilizing planes in order to facilitate the control of the aeroplane.

A Gas Container that Forms a Parachute.—Albert A. Callicotte, of North Yakima, Wash., has patented, No. 1,092,973, an airship in which the gas container is shaped as a parachute. Horizontal and vertical tubes are provided in which are arranged the propelling and elevating means.

The Aeroplane and the North Pole.—The report comes from Berlin that Capt. Roald Amundsen has completed a course of training as an air pilot at Johannisthal. He will take with him two aeroplanes on his polar expedition, hoping to reach the pole by air after travel by sea becomes impossible.

Hirth's Flying Machine.—Hellmuth Hirth, the well-known German aviator, has secured patent No. 1,094,898 for a flying machine, the different parts of which are arranged so that the lifting power may be rapidly and easily adapted to the load carried, and the speed of flight to the local circumstances, for instance, those present in landing.

A Tax on Aviators.—An entry and circulation tax upon aviators in Germany is not likely to be favored in aeronautic circles. It is now being considered by the Foreign Office, and applies to all outside aeroplane pilots with their machines, somewhat like the rules which exist in Alsace-Lorraine as concerns automobiles. The tax will be $12.50 and even $25 per pilot, regardless of whether he enters by railroad or by actual flight.

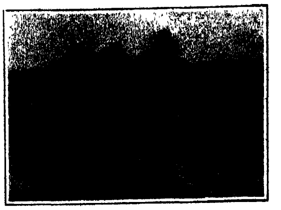
An Aeroplane Review.—During the visit of the English sovereigns to Paris, one of the interesting events was the army review held at the Vincennes military grounds, and on this occasion aeroplanes were out in force. During the maneuvers pilots made a sham attack upon the airship "Montgolfier" which is the "Clement-Bayard VI." rebaptized, and as the airship itself is remarkably easy to handle, such an attack brought out the pilots' skill, and showed what we might expect in real war. The whole maneuver was a great success and is a very novel performance with the two kinds of aircraft. Farman biplanes were used entirely in this case, most of them equipped with De Dion motors.

The Russian Programme.—According to latest news about military aircraft matters in Russia, it appears that the war department has made a number of changes in the programme which is proposed for construction of new aeroplanes. The new programme in fact calls for building 100 aeroplanes of the Deperdussin, and the same number of the Morane type, as well as 40 Farman aeroplanes, making 240 flyers in all. On the other hand, the number of Sikorsky aeroplanes which are to be built by the Russo-Baltic establishment is considerably reduced, for at first it was proposed to build about 100 flyers of this type, but the present programme calls for only 45. Of this number, 25 will be biplanes, 13 monoplanes, and the remainder will be used as teaching apparatus without motors.

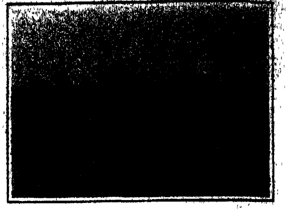
Aviation in Russia.—The general assembly of the committee of the Russian aerial fleet was held not long since, presided over by Grand Duke Alex. Michailovitch, and it was decided, first, to organize corps of aerial militia which will add volunteer aeroplane pilots in order to reinforce the army and navy fleets; second, to establish military aviation stations provided with strong electric searchlights; third, to form a corps of aeroplanes which are to act as a reserve in order to supply the main fleet with all that is necessary in time of war. As regards Russian aeroplane events, we note that Prince Abamalek has offered a prize of 10,000 roubles for a successful flight from Sebastopol to St. Petersburg during May or June, the trip to be made within 24 hours. Although this time may appear short, it is claimed that during the good weather that prevails at this season, the trip can be made without undue difficulty in that length of time.

Armored Aeroplanes for France.—A fleet of armored aeroplanes is being prepared for the use of the French army, according to recent statements made by the Minister of War, and it is designed to serve mainly for scouting purposes. Before long a fleet of the new aeroplanes is to start from the Chalais-Meudon establishment for the Mailly camp where the final trials are to take place. Such flyers are biplanes and have two places, being built according to Comm. Dorand's designs. The armored body or fuselage holds pilot and passenger who are protected by a 2½-millimeter steel plating, and it is claimed that it cannot be penetrated farther than 2,500 feet. In front is the motor of 85 horse-power size, and the speed will be about 60 miles an hour. According to a well-known expert, the present flyers are the only armored aeroplanes that have been able to satisfy the requirements for this class of flyer. Six aeroplanes will make up the present fleet, and they will be manned by well-known pilot officers.

One of the screw type guy anchors.



Making fast to the shifted track.



The track restored to the original position.

Hauling a Flood-swept Railroad Back to Line

SECTION gangs on the Louisville and Nashville Railroad last spring performed the unique feat of hauling back into place six miles of railroad track that had been washed away by the floods. For about three miles on either side of the Wabash River the high water had not only shifted the tracks and ties, but in some places had upended them against the telegraph poles, so that they resembled a grotesque picket fence that had been hit by a cyclone.

The method used in working the track into position while the waters were still running over the right of way was as follows: A dozen 12-inch guy anchors were rushed to the scene of trouble, the sort that can be screwed into the ground, and offer a secure anchorage against heavy strains. With the water running from a foot and a half to three feet deep, these anchors were screwed into position along the shifted railroad tracks, upstream from the right of way. A block and tackle was passed through the eye of each anchor and around the railroad track and then twenty or thirty laborers would tug on the fall line until the section was slowly worked into position. It was then staked down to prevent further shifting, the anchors were unscrewed and the operation was repeated. Not only the dead weight of tracks and ties, but the resistance of the current made a terrific strain on the devices thus brought into unexpected use, but they proved to be decidedly effective, so that about two thousand feet of track was relaid every day, as against six to seven hundred feet by previous methods.

The photographs show the details of the operation and indicate the unusual difficulties under which the section hands were operating.

Electric Towing Locomotives for Panama Canal Locks

THE first lot of electric towing locomotives for hauling vessels through the locks of the Panama Canal are now being received at the Isthmus. In all, forty of these "electric mules" are being built by the General Electric Company for this purpose. The machines weigh 82,500 pounds; measure 32 feet 2½ inches long by 8 feet wide by 9 feet 3 inches the greatest height over the cabs; have an available tractive effort as high as 47,500 pounds and a windlass rope pull of 25,000 pounds, and four of them, two on each side, will ordinarily propel steamships through the locks. Sometimes six engines will be needed to handle extra large vessels; in every case two astern, acting as a brake on the ship's movements, will give direction to her course. No vessel will be allowed to enter the locks and go through on her own power.

The locomotive is propelled by means of a rack rail while towing and while going up or down the steep grades from one level to another at a speed of 2 miles per hour. While running idle or on return tracks, the speed is changed to 5 miles per hour, and the machine is propelled by the regular traction method, the rack pinion being entirely released. This change is effected by manually-operated clutches located in the gear mechanism in connection with a lever in each cab similar to a steam locomotive.

The locomotive is driven by two 75 horse-power totally inclosed motors of the mill type, one being direct connected through reduction gearing to each axle. Three-phase, 25-cycle, 220-volt current is used, and is collected by contact plows. The motor and traction gearing is mounted on a common base-plate, which in turn is mounted on a driving axle and spring suspended to the locomotive frame the same as in regular railway practice.

One of the towing locomotives for the Panama Canal locks.

In the center of the locomotive is located a vertical windlass with drum, the capacity of which is 800 feet of 1-inch steel hawser cable. The windlass, with its driving motors and gearing, is mounted on a solid base-plate, and is likewise independent of the movement of the locomotive frame. The cable drum extends above the locomotive cover and has a floating guard placed around it to retain the cable while coiling loose.

The windlass cable is handled by two 20 horse-power motors, also totally inclosed and of the mill type. One is geared for a rope speed of 12 feet per minute at a pull up to 25,000 pounds at 2 foot radius, and its function is to adjust the position of the ship for anchor or while being towed through the locks. The other motor is geared for a rope speed of 200 feet per minute at 2-foot radius, and its duty is to take up slack or pay out cable or wind in any part of the entire length of cable as may be required. The cable drum is driven through a friction device which can be set at any desired value from zero up to the full capacity of the motor.

Freak flying machine built on the principle of the boomerang.

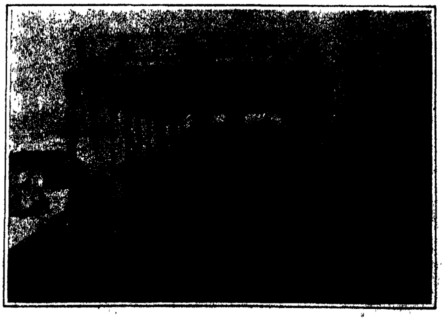
A "Boomerang" Flying Machine

TWO French engineers, A. Papin and D. Pouilly, are responsible for a new departure in aeronautics—a departure that has not yet departed from the solid earth. They explain that in designing their machine they had before them mainly three purposes: To provide a device which could rise from the ground without preliminary "run," and which could similarly alight on a selected spot; to furnish a machine that could at will either advance through the air or be held stationary; to provide for a slow descent in case of failure to the motor.

The apparatus is designed on the principle of the boomerang, or, to use another illustration, of the maple seed, which represents a natural example of a screw propeller revolving about an imaginary axle and capable of assuming different inclinations. The fall of the maple seed is familiar to all, how it slowly descends, revolving about its axis as it does so. If the direction of its rotation were reversed by the application of suitable power, the seed would rise instead of falling.

Our illustration shows the new "flying machine." It constitutes a huge single blade screw propeller with a spread of 178 feet. The blade *A* and the central body *B* are hollow, and through them a stream of air is blown by a fan *C*, driven by a motor *D*. The motor is an 80 horse-power, nine-cylinder gasoline engine, and is manipulated by compressed air controls from the car, which does not participate in the rotation of the rest of the machine. The blast of air escaping from the curved tip of the propeller at *G* causes it to revolve by impulse reaction. The car *J* is mounted on ball-bearings. Over it is situated a hollow antenna *K*, the tip of which is curved in the direction opposite to that of the tip of the propeller blade. Through this hollow antenna a blast of air is also blown, issuing at the nozzle *L*.

The new device is, without doubt, interesting—from a psychological point of view. But—will it fly? Perhaps this is a secondary consideration.



Sight-seeing barge for the Panama Canal.

Sight-seeing Barge for the Canal

THE greatest sight-seeing conveyance for public use is the passenger carrying barge fitted up to make trips through the Panama Canal. Its foundation is a steel dump barge, brought to the Isthmus in 1909, which is 154 feet long, with a 32-foot beam, 10 foot 7 inch depth. It has a gross displacement of 509 tons.

Like the familiar sight-seeing automobiles, the seats are arranged in tiers, gradually descending from a height of 8 feet 9 inches in the rear to 2 feet at the forward end, and there is also standing room for the passengers on the roof.

The Paper Used by the Government printing office each year requires approximately 125 million pounds of rag pulp and 490 million pounds of wood pulp.

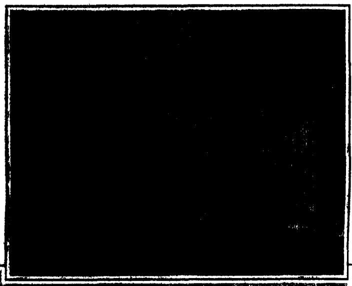
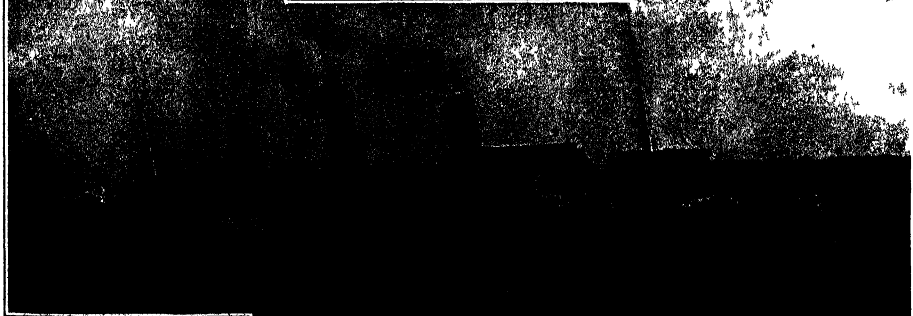
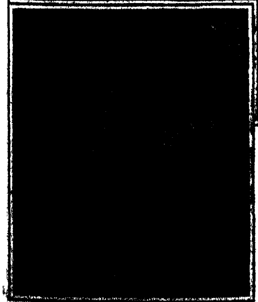
The World's Largest Steamship

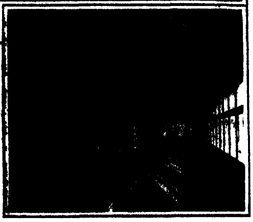
Maiden Voyage of the Steamship "Vaterland," to the Port of New York

WITH the launching of each 'largest steamship it was customary a few years ago to say of her that the limit of size had been reached and that in future there would surely be a return to more moderate dimensions. To-day, we hear no such prognostications for the dimensions so far from diminishing give promise rather of increasing It was less than one year ago that there steamed into the port of New York the Imperator' of the Hamburg American Line—the first ship to exceed a length of 900 feet her length on deck being 909 feet and her displacement 52 000 tons. This week sees the advent of the Vaterland of the same company a huge ship which exceeds the Imperator' in length by 41 feet in beam by 2 feet and in displacement by no less than 6 000 tons









The dining room seating eight hundred people

The "Vaterland" leaving Hamburg for her trial trip.
Length 950 feet; beam, 100 feet displacement 58 000 tons

Cruiser stern and balanced rudder.

A stretch of deck, showing wind screens.

The Vaterland whch was built at the yards of Blohm & Voss, Hamburg, is 950 feet in length 100 feet in beam and she displaces 58,000 tons. We are informed bv the company that during a trial cruise of over two days' duration she averaged a speed of 25.8 knots, her turbiues developing 90,000 horse-power In view of the fact that she was announced as a 23-knot ship this is certainly a most surprising result, although the great work which has been done by her builders in the construction of high-speed German armored cruisers propelled by similar motive power, all of which greatly exceeded their contract speed, should have prepared the public for very fine steaming results in this vessel Thus the Von der Tann designed for 25 knots made on a recent trial 28.1 knots the Moltke and Goeben designed for 27 knots on recent runs made respectively 28.7 and 28.6 knots The motive power of the Vaterland is broadly similar to that of the cruisers consisting of four turbines driving four propellers

As compared with the Imperator which was built at the Vulcan Works the Vaterland to the eye of any but the expert looks to be practically identical her increase in length of 41 feet being scarcely perceptible on a ship of such great dimensions Her under water form however and the construction of the hull at the stern are quite different the Vaterland having what is known as a cruiser stern with a balanced rudder which is entirely below the waterline The form of the

"Vaterland" also differs greatly from that of the "Imperator," the successive water planes aft being fuller than those of the earlier ship. We understand that the changes in her model, as compared with the "Imperator," had much to do with the high speed which she achieved on her trial. A feature which adds to the appearance of the ship is the absence of the monster eagle which is carried at the bow of the "Imperator." An eagle makes an appropriate figurehead on a clipper-bowed ship; but it is inappropriate and quite inharmonious when placed at the top of a straight stemhead such as characterizes the modern transatlantic liner. The shield and scroll work of the "Vaterland" are in better taste.

The "Vaterland" is constructed with both longitudinal and transverse bulkheads, the longitudinal bulkheads forming the inner walls of the coal bunkers, and serving as an inner skin. All the walls of the passenger decks have been coated with special fireproof material. The bulkheads are of unusual stiffness, and the openings in them, where they pass through the passenger accommodation, are closed by fireproof glass doors, thirty-nine in number, which will withstand a temperature of 1,000 degrees. The staircases are so encased with fireproof material that each forms a fireproof inclosure. A special fire department, composed of trained fire fighters, devotes its entire attention to fire protection. It occupies a special cabin, where all the fire alarm signaling devices are centered. There are more than 450 fire announcers throughout the ship, which would instantly indicate a dangerous rise of temperature. A complete system of automatic fire sprinklers, comprising 800 water jets, is distributed throughout the crew's quarters. A special fire fighting device employing chemicals in place of steam is operated by the firemen. There is also a complete system of fire hose and pumps. The fire fighting installation fulfills the strictest rules laid down by the German building and police authorities. The "Vaterland" carries eighty-four lifeboats, including two motor lifeboats, which more than accommodate all on board.

The several cabins of the "Vaterland" have been designed by the leading decorators of Europe; and the great liner with its paintings, sculptures, and decorations affords an interesting study of the decorative arts. The grand dining saloon, which seats 800 guests, is finished in white and gold, its ceiling being supported by Ionic columns. In contrast to this the Ritz Carlton is carried out in mahogany and walnut, decorated with heavy garlands in bronze. The smoking-room is paneled in Flemish oak in low tones, while the main lounge, which may be converted into a ballroom, is decorated in warm red tones. The art treasures include paintings by old Italian masters as well as work of many notable contemporary artists. On the main staircase hang two landscapes by the Venetian artist, Giovanna Battista Pittoni (1690-1767). Four large canvases by Lairesse adorn the main saloon; and a portrait of King Ludwig of Bavaria, by Baumgartner, will be found in the ladies' saloon. The smoking-room is enriched by two marine studies by Prof. Schnars-Alguist, while a great panoramic study, by Kolmsperger, adorns the cupola of the dining-room.

The Death of Paul Louis Heroult

A PRIVATE cable to students of the Massachusetts Institute of Technology announces the death in Paris on Saturday of Paul Louis Toussaint Heroult, whose name will ever be connected with aluminium and the electric furnace. The name is familiar in Boston in that his son Paul was a student at the Massachusetts Institute of Technology from 1910 till 1912, going home at the end of his sophomore year for his service in the army. He was particularly active in athletics, being on the tug-of war team, second in the pole vault and one of the wrestlers.

Heroult *pere* was born at Thury-Harcourt, and had his boyhood schooling about equally in England and France. He went to the Lyceum at Caen and later to St. Barbe, Paris. In 1882 he attended the School of Mines in Paris, and the next year took his military service in the army. On finishing this he went with a metallurgical firm, and giving his attention to aluminium, in 1886, two years thereafter, he obtained a patent for the production of this metal electrolytically. On his discoveries are based the improvements in methods that brought the price of the metal from $20 a pound in 1884 to about 50 cents in 1901.

The more recent achievements of Heroult have been in the line of the electric furnace for steel, aluminium and other metals. His principal work here was the introduction of two electrodes into the melting-pot, so that the ore received the full effect of the heat and the furnace was little more than a container. A later improvement consisted of a third electrode, which was in the nature of a starter and which burned away when the furnace rose to its proper heat. For his furnace he received in January, 1904, the medal of the French Society for the Encouragement of National Industries. The Heroult furnace is in extended use to-day in many places, while for Canada he made a special investigation with the nature of the local ores in view.

Do Plants Sleep?

By Maud DeWitt Pearl

WE ordinarily think of the ability to sleep as something belonging exclusively to the animal kingdom. Whether plants likewise enjoy a daily period of rest has recently been studied by a distinguished Indian botanist, Prof. Bose, of Presidency College, Calcutta, India. He worked with the sensitive plant, *Mimosa pudica*. An electrical apparatus was constructed, which, at regular intervals throughout the day and night, gave a slight but constant shock to the plant. When the plant responded to this stimulus it drooped its leaves and stems. Then, after a period of quiescence, it gradually returned to its original condition. The degree of response to the electric current and recovery to the normal condition were recorded upon a smoked glass plate by means of a tracer attached to the apparatus, so that an hourly record was obtained, for many days and nights, of the state of the "motor-excitability," as Prof. Bose terms it, of the plant. The results which were obtained show that Mimosa is in the Land of Nod, regularly, every day. What is true of Mimosa is undoubtedly true for plants in general.

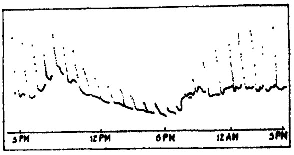


Fig. 1.—*Diagram showing response of Mimosa to stimulation during a period of twenty-four hours.*

If it had not been for Prof. Bose's experiments, however, no one would have suspected that plants are guilty of disobeying the old adage of "early to bed and early to rise," etc. But the experiments show Mimosa to be a very late sleeper. At nine o'clock in the morning the plant is practically unresponsive when stimulated by the electric current. From this time on, however, there is a gradual awakening until at noon the maximum response is reached. This continues until about five o'clock in the afternoon, when the fluctuation toward the opposite condition sets in. The motor-excitability gradually diminishes until the minimum state is reached at about nine o'clock the following morning.

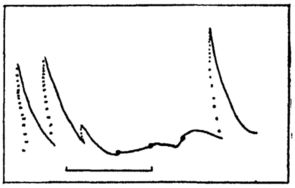

Fig. 2.—Response when subjected to sudden cold.

This variation of the motor-excitability of the plant is due to the combined effect of light, temperature, and moisture. During the night the temperature is lower, the stimulating effect of light is withdrawn, and the plant becomes more turgid, owing to its not giving off so much moisture. Since the effect of these factors upon the plant is cumulative and at the same time there is a lag in the response of the plant to them, we have the explanation of why Mimosa is in a state of lethargy so late in the morning. Likewise, why the plant is in the opposite condition late in the afternoon when night is fast approaching.

The accompanying drawing, Fig. 1, shows the state of excitability of Mimosa during a period of twenty-four hours when stimulated regularly by the electric current. The diagram is read from left to right. The uneven base line is due to the regular leaf movements which the plant exhibits daily and is not related to the response of Mimosa to the electric current. The downward curve represents the gradual recovery from the stimulus. It will be noted that the plant is markedly excitable from 12 A. M. up to about 9 P. M. From this time on there is a gradual [illegible] stimulation until late in the morning, when the plant shows no excitability whatever. After this time the recovery is quite rapid up to 12 A. M., when the [illegible] of excitability is reached.

Fig. 2 shows the amount of response to the electric current when subjected to sudden cold. The dotted upward lines indicate the degree of response to the stimulus, the smooth downward lines, the recovery. It will be noticed that after the plant is exposed to sudden cold the first response to the current is much lessened, and the second and third stimulations produce no effect whatever. The ordinary temperature is then resumed, but the plant still exhibits the after-effects of the cold.

Setting a Watch

By Frederick R. Ward

THE accurate time signals sent out by wireless at noon and at 10 P. M. from the Government station at Radio, Va., have stimulated the interest of those who are equipped with receiving apparatus in keeping their watches closely regulated and set.

Watch movements as good as the 17 jewel grade, and costing about $15, may, by careful adjustment of the regulator, be made to keep time to within thirty seconds per month; so that, if a curve be plotted on cross-section paper showing the error of a watch, each time it is checked by the wireless signal, it is possible to estimate closely what the error should be at any given time.

Since, however, an exact adjustment of the regulator is impossible and the error gradually increases until it becomes inconveniently large, it is often desirable to reset the hands. The usual method of doing this, by stopping the balance wheel with a toothpick and letting it go at the right moment, is inconvenient unless there be another time-piece at hand and is also open to other objections.

The author has discovered a method of bringing the error back to zero, or of setting a watch accurately without disturbing it in any way. If the chain or fob be removed, and the watch be hung up by its bow on a hook or nail driven in the wall, so that it hangs free, it will be found to swing itself slightly, pendulum fashion, by reason of the motion of the parts of the escapement. The effect of this swinging on the running of the watch varies between individual watches and depends on the weight of the case and on its dimensions. As a rule, it will be found that a watch gains about two seconds per hour, though some of them show a loss, instead. The exact amount must be found by trial, say, by hanging up the watch for ten hours and checking it against the wireless signal. Once this value is known it is obvious how it may be used to advantage. If the watch *gains* when hung up, the regulator should be adjusted so as to make it run a trifle *slow*. Then when the accumulated error becomes inconveniently large, the watch may be hung up on the hook, say at night, for the right number of hours to bring its second-hand ahead to the correct position.

Should a watch be found of such weight and dimensions as to neither gain nor lose when hanging as described, it can be made to respond by hooking on a piece of metal at the base of the stem, thus raising the center of oscillation of the swinging mass. For the same reason a hunting-case watch has a different rate when hung with its case open from the one when the case is closed. It is an added convenience to know both these rates, since sometimes one is positive and the other negative, thus enabling one to set the watch either forward or backward at will.

Our Front-cover Illustration

AS evidence that the giant ocean liner is profitable, it should be noted that there are five vessels of 900 feet length and over building or under construction. These are the "Vaterland," 950 feet; "Imperator," 900 feet; a sister to the "Vaterland" building at Hamburg; the "Aquitania," 900 feet, which will reach New York in June; and the "Britannic," 900 feet, shown on our cover, due here next Autumn.

Ross writes on Houseflies and Disease.—H. J. Spinden tells us the story of an interesting chapter of ancient American history.—Bashford Dean writes on the habits of fishes, as illustrated by exhibits in the American Museum of Natural History.—A paper read by W. A. Hargreaves before the Society of Chemical Industry on "Blasting Gelatines" is reported in full.—A timely topic discussed is that of disease danger in the invasion of Mexico.—The use of trees as windbreaks for farms is illustrated and described.—A chart prepared by C. H. Clark shows at a glance the [illegible] to transmit a given horsepower at [illegible]

The Fallacy of the Combined Aeroplane and Dirigible Balloon

By [illegible]

THE reason for proposing a combination of balloon and aeroplane is not hard to find. Probably the inventor reasons something like this: "The aeroplane is inexpensive, compact and speedy; but it is unsafe, and will not carry much weight. The dirigible is big, clumsy, expensive and slow; but it is safe, and it will carry a comparatively large weight. Let us combine the two principles in such a way as to get the advantages of each without the disadvantages. Let us attach to an aeroplane a balloon bag which is large enough to carry part of the weight and let the machine down slowly in case of accident, but will not be so big and offer such resistance to speed as a regular dirigible which has to lift all of the weight unassisted. Then the aeroplane will also be big enough to carry the machine safely to the ground in case the balloon explodes."

This is what is generally meant by a "Combined Aeroplane and Dirigible"; that is, a combination, each unit of which can carry a considerable part or all of the weight. Aeroplane surfaces on dirigibles for steering purposes, or as a substitute for ballast, are in an entirely different class and are practically necessary in some form. Then there is the entirely feasible, though perhaps not practicable, method of *balancing* an aeroplane by means of a balloon; these forms will be considered outside of the present sphere of discussion.

The arguments given above for the combination machine might seem very reasonable. They are. The only trouble is that it doesn't work out that way. The argument is all right, but the premises are wrong. Most of the fallacies in such a scheme arise from disregarding one or more of the following laws:

1. There is no object in combining two *different* methods for attaining a given result unless some added advantage peculiar to such a combination is gained. Thus you wouldn't ordinarily hitch a gas engine and a steam engine in tandem to drive a dynamo, but would select the most efficient unit for that particular work, and use it exclusively. On the other hand, the combination of a reciprocating engine with a turbine is often better than either one alone because, although not so efficient at high pressures, the turbine can get energy out of the exhaust steam which would otherwise go to waste.

2. The volume and hence the lift of a balloon varies as the cube of its outside dimensions. Much trouble is caused by a misconception of the size necessary to lift any considerable weight. There *are* balloons which will carry a large weight but they are all very much bigger than any aeroplane ever attempted. A dirigible 260 feet long by 50 feet in diameter will lift a total of 26,000 pounds when inflated with hydrogen. A balloon one tenth these dimensions would be 26 feet long by 5 feet in diameter, comparable in size to the ordinary aeroplane; yet it would barely lift itself, a total of 26 pounds.

3. For small sizes, the resistance and weight of a balloon vary as the square of its outside dimensions.

4. It takes exactly as big a balloon to keep a given weight from falling as it does to lift it. As a close corollary to this, we have that it takes nearly as much gas to let a weight down easily as it does to lift it.

5. The lift of an aeroplane varies as the square of the dimensions while its weight and resistance (for structural reasons) must vary by a little more than the square. Furthermore, the efficiency of a surface is very much impaired by extending or multiplying it from front to rear, which is just the opposite to the case of the dirigible. (In spite of this, the aeroplane can probably be developed considerably above its present size.) The efficiency of an aeroplane decreases slightly with increase in size. Not so with the dirigible. It is fundamentally and always will be a large machine. The results to be gained by even a moderate increase in size are almost inconceivable at first; but it is founded on strict elementary laws which cannot be ignored any more than the existence of gravitation.

As an actual example, let us figure out roughly how much we can improve an ordinary Wright aeroplane by the addition of a cigar-shaped balloon which will lift half the weight. I think we may take the performance of the aeroplane alone about as follows: Horse-power, 30; speed, 40 miles per hour; resistance (thrust) 180 pounds; efficiency of power unit, 64 per cent; total weight with fuel and 2 passengers, 1,000 pounds.

Take away half the supporting surface, which might reduce the weight to 800 pounds, and the resistance to 120 pounds, for the same speed. A balloon 60 feet long by 12 feet diameter would have a total lift of 780 pounds when fully inflated with hydrogen. Its weight with suspension cords, framing and accessories would be in the neighborhood of 380 pounds, thus leaving 400 pounds for lift, or half the weight of the reduced size aeroplane. Its resistance, with extra bracing, etc., would be close to 300 pounds at the 40 mile speed. The speed of the combination would be cut down in consequence to about 20 miles per hour, and the lift of the aeroplane to 170 pounds. We lose, in this way, 230 pounds of lift that we had counted on from the aeroplane. It means that instead of cutting down its size to meet the new conditions, *we should have actually increased it* by 3 or 4 times its original area. After making these corrections, we get final results something as follows: Speed, 20 miles per hour; total weight, 1,600 pounds; lift of gas-bag, 800 pounds; lift of aeroplane, 800 pounds.

We have reduced our speed to one half that of the original aeroplane. We have a machine which is clumsier, more expensive and slightly less speedy than a regular dirigible of equal power and passenger carrying capacity. Certainly such a sacrifice should be accompanied by some very great advantage, but where is it? Take the matter of safety. Suppose the machine were to lose headway and fall vertically. The area resisting the descent consists of the superposed aeroplane surfaces and the horizontal surface of the balloon, which are about 1,500 and 900 respectively. The most favorable possible calculation would give a speed of descent of 20 feet per second, hardly a *safe* velocity at which to strike the earth.

Instead of taking the horse-power the same in the above example, we could have assumed equal speeds for the two machines and increased the power to suit; but the results in the latter case are equally significant and still less effective in producing safety.

The scheme of making the balloon bag itself in the form of an aeroplane seems still less promising. If the balloon were distorted enough to give it any efficiency as an aeroplane surface its weight and resistance would be prohibitive. I shall touch on this a little more fully in the paper on double balloons.

It *might* be possible to provide a regular dirigible with enough aeroplane surface to carry it safely to earth in case of an explosion; but there is no need for it. Such an accident very seldom occurs, and it is easily prevented by taking proper precautions. Such a large surface would be very heavy, and offer much resistance even when folded up. Then consider, for example, the difficulty of constructing and managing a set of aeroplanes big enough to carry a large dirigible, which would be suddenly called upon in an emergency to support 15 to 20 tons. Such an accident is much better taken care of by prevention in the first place. As a last resort, I would suggest individual parachutes for the passengers.

Changes in the Patent Office Rules

ACTING with the approval of the Secretary of the Interior, the following changes are made in the Rules of Practice in the Patent Office to take effect May 13th, 1914:

Rule 101 is amended to read:

101. Upon the institution and declaration of the interference, as provided in Rule 102, the examiner of interferences will take jurisdiction of the same, which will then become a contested case; but the law examiner will determine the motions mentioned in Rule 122, as therein provided.

Rule 109 is canceled and the following substituted in its place:

109. An applicant involved in an interference may, at any time within thirty days after the preliminary statements (referred to in Rule 110) of the parties have been received and approved, on motion duly made, as provided by Rule 153, file an amendment to this application containing any claims which, in his opinion, should be made the basis of interference between himself and any of the other parties. Such motion must be accompanied by the proposed amendment, and when in proper form will be transmitted by the examiner of interferences to the law examiner for his determination. On the admission of such amendment, and the adoption of the claims by the other parties within a time specified by the law examiner, the primary examiner will re-declare the interference, or will declare such other interferences as may be necessary to include the said claims. New preliminary statements will be received as to the added claims, but motions for dissolution will not be transmitted in regard thereto where the questions raised could have been disposed of in connection with the admission of the claims. Amendments to the specification will not be received during the pendency of the interference, without the consent of the Commissioner, except as provided herein, and in Rules 106 and 107.

Rule 122 is amended to read:

122. Motions to dissolve an interference (1) upon the ground that there has been such informality in declaring the same as will preclude a proper determination of the question of priority of invention, or (2) which deny the patentability of an applicant's claim, or (3) which deny his right to make the claim, or (4) which allege that counts of the issue have different meanings in the cases of different parties, should contain a full statement of the grounds relied upon, and should, if possible, be made not later than the thirtieth day after the statements of the parties have been received and approved. Such motions, and all motions of a similar character, should be accompanied by a motion to transmit the same to the law examiner, and such motion to transmit should be noticed for hearing upon a day certain before the examiner of interferences. When in proper form the motion presented will be transmitted by the examiner of interferences, with the files and papers, to the law examiner for his determination, who will thereupon fix a day certain when the said motion will be heard before him upon the merits, and give notice thereof to all the parties. If a stay of proceedings is desired, a motion therefor should accompany the motion for transmission.

When the motion has been decided by the law examiner the files and papers, with his decision, will be sent at once to the docket clerk.

Motions to shift the burden of proof should be made before, and will be determined by, the examiner of interferences. No appeal from the decision on such motions will be entertained, but the matter may be reviewed on appeal from the final decision upon the question of priority of invention.

Rule 124 becomes:

124. Where, on motion for dissolution, the law examiner renders an adverse decision upon the merits of a party's case, as when he holds that the issue is not patentable or that a party has no right to make a claim, or that the counts of the issue have different meanings in the cases of different parties, he shall fix a limit of appeal not less than twenty days from the date of his decision. Appeal lies to the Examiners-in-Chief in the first instance and will be heard *inter partes*. If the appeal is not taken within the time fixed, it will not be entertained, except by permission of the Commissioner.

No appeal will be permitted from a decision rendered upon motion for dissolution affirming the patentability of a claim, or the applicant's right to make the same, or the identity of meaning of counts in the cases of different parties.

Appeals may be taken directly to the Commissioner, except in the cases provided for in the preceding portions of this rule, from decisions on such motions as, in his judgment, should be appealable.

Rule 128 is canceled and the following substituted in lieu thereof:

128. *If, during the pendency of an interference, a reference* be found, the primary examiner shall call the attention of the law examiner thereto, and the latter may request the suspension of the interference until the final determination of the pertinency and effect of the reference, and the interference shall then be dissolved or continued as the result of such determination. The consideration of such reference shall be *inter partes* and before the law examiner.

Looping the Loop

A Pilot's and a Passenger's Impressions

LOUIS NOEL'S impressions of "looping the loop" in a flying machine are thus recorded in *Flight*: "There are no words in which to express the sensation. As it is, the ordinary flight is quite exhilarating, but this new stunt quite exceeds everything in the world; in fact, in a word it is super-human. When once you have done it you feel you must repeat it again and again; you are so intoxicated with the wonderful sensation. You start off, and rise to a height of between 600 feet and 700 feet, and then you can begin the joke absolutely without danger After executing a gentle *vol piqué* you pull the lever back, and the 'bus leaps with tremendous speed upward—which it loses at the zenith of the loop. At this moment you are completely isolated from the earth and you can see nothing but the planes. Then it is that an incomprehensible sensation runs through you at being absolutely alone, suspended by an invisible string amid air. I assure you it is a unique position; nothing to fear—only happiness. All this of course (unfortunately) is done and finished in a second or so, and, after diving again, you have the first glimpse of the earth under you and you can only regret that the looping is over There is just one thing to consider, however; I think that if I 'loop' often I shall lose that wonderful feeling."

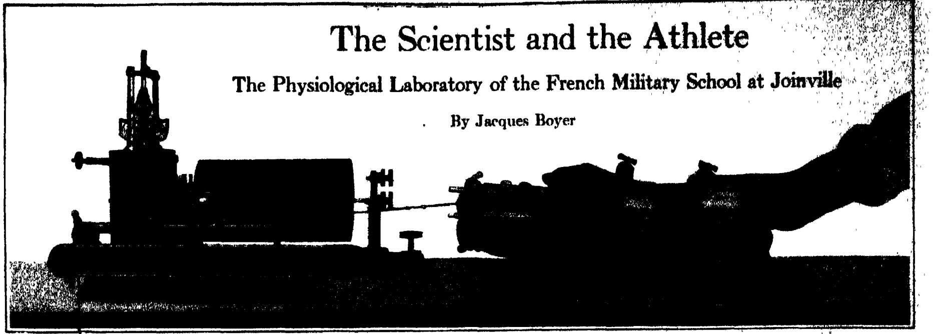
A passenger whom Noel took up in an 80 horse-power Le Rhone-Morane-Saulnier machine says in the same issue of *Flight*:

"My own impressions of looping are much the same as Noel's, but there is one point that has struck me particularly, and that is the fact that I could not realize that I was upside down. I did not feel any tendency to fall out, and if I had shut my eyes I would not have known, for the greater part of the time, that we were not flying normally. Before I ascended I took the precaution of seeing that what little coin of the realm I had in my pocket would not fall out when in an inverted position, but, as I found later, quite unnecessarily, for, once in a way, my money remained quite securely in my pocket. As far as I can put it in words, my sensations from start to finish were as follows: After climbing to a height of about 600 feet, Noel turned and inquired if I was ready, and then we dived slightly, the feeling in this case being similar to that during a *vol plané;* the ground stretched out before us, then suddenly 'rolled' out of sight as the nose of the machine was turned upward, and there was nothing but the clouded sky all round. The rush of wind, which had been intense, then seemed to die out altogether for a second or so, and now one felt that wonderful feeling Noel spoke of, of being absolutely alone and extraordinarily happy. The next sensation was exceptionally weird, for suddenly there was a terrific rush of air and the earth came into view from behind and above, and passed with startling rapidity in front of the machine, just as if some one had thrown a roll of green cloth over one's head from behind, so that it unrolled as it went. As the ground passed from overhead to the front of the machine, the sky again came into view overhead, coming up from behind as did the earth, and I realized then that we were diving and that we had been upside down All this time I felt absolutely comfortable in my seat, and it was only when we were recovering our normal position that I felt any rough movement. Each time we made the loop we came out of the top of it slightly sideways, so that when the horizon line appeared above our heads it was not absolutely horizontal. As I said before, although I saw, for the space of two or three seconds, the ground stretched out above my head, I had no feeling of being upside down."

The Scientist and the Athlete

The Physiological Laboratory of the French Military School at Joinville

By Jacques Boyer



The Mosso ergograph, which registers the work done by the fingers.

AT the normal fencing and gymnastic school which the French war ministry maintains at Joinville, systematic physical training is given to officers and men, and methods of improving the physical condition of the men of the auxiliary service are investigated. Especial attention is given to perfecting the exercises and methods of training, with the aid of scientific researches carried on in the physiological laboratory of the school.

In addition to the counting and recording instruments which are commonly employed by physiologists and psychologists for the study of respiration, circulation, and muscular contraction, the laboratory contains several novel and interesting instruments invented by Prof. G. Demeny for the determination of the form and dimensions of the body at rest and in movement. The laboratory is also well equipped for work in photography, including chrono-photography and kinematography.

The dimensions of the thoracic cavity are measured with calipers having blunt tips of ivory. One of these tips is affixed directly to one leg of the instrument, but the other tip is attached to a rod which can move in a graduated slide against the pressure of a spring. This construction allows the calipers to be withdrawn without opening them or wounding the subject. When the instrument is applied to the chest the spring tip remains in contact with the body without interfering with respiration, so that the travel of the rod measures the augmentation of the thoracic diameter in the act of inspiration. By connecting the rod with a pair of Marey capsules, a continuous record of the variations in diameter can be inscribed on a rotating cylinder.

In order to obtain more precise measurements of all dimensions of the body, Prof. Demeny has devised an instrument, the double universal conformator, which can be adjusted to trace on paper outlines of the median vertical section of the trunk, and of horizontal sections at various heights. The essential organ of this apparatus is a metal rod, to which numerous thin strips of wood, forming a continuous series, are attached transversely in such a manner that each strip can move independently in a direction parallel to its length (or at right angles to the rod) and that all the strips can be fixed in position by turning a nut at the end of the rod. The ends of all the wooden strips are brought into contact with the body, and the nut is screwed down. The contour of the body can be traced on paper from the profile of the strips thus immobilized.

With two such rods, mounted parallel to each other on suitable supports, the form of horizontal sections of the body, or of its lateral or anterior and posterior vertical profiles can be determined very quickly. Complete horizontal sections of the chest at various levels are obtained by attaching four rods to a rectangular frame, inside which the man stands on a platform which can be raised to any desired height.

The Demeny conformator reveals immediately and without calculation any defect of symmetry, such as unequal height of shoulders or hips, abnormal curvature of the spine, etc.

For the special study of the spine an instrument called a sachigraph or profilograph has been devised. Four rods, connected by movable joints to form a rhomb, are supported by a carriage that moves in a slot in a vertical post. The subject stands with his back to the post, and the carriage is moved upward, while a blunt point attached to one vertex of the rhomb is pressed against his spine. Simultaneously, a pencil attached to the opposite vertex of the rhomb traces the profile of the spine, in its true dimensions, on a sheet of paper.

Vertical sections are obtained also by an instrument which traces the profile on paper by means of pencils attached to two rods, mounted on rollers, between which the subject is placed, and which measure the thickness of the body at every point as they move up or down.

The volume of air introduced into the lungs by a deep inspiration is measured by a very simple spirometer. The inhaled air is expelled through a rubber tube into a cylindrical bell-glass, which dips into water contained in a larger glass vessel. The cross-section of the tube is made equal to that of the trachea in order to minimize resistance and disturbance of the rhythm of respiration. The bell-glass is suspended by a cord which passes over two pulleys and has a counterpoise attached to its other end. The bell-glass rises as the air is blown into it, and if its wall were infinitely thin its rise, indicated by the emergence of an attached scale from the water, would be exactly proportional to the volume of air introduced, the pressure remaining constant. In practice, however, there is a small increase of pressure, which is measured by a manometer inside the bell-glass and is applied as a correction. The spirometer is calibrated by injecting air in measured quantities, one liter at a time, and reading both the water level scale and the manometer after each addition.

Many of the physiological researches that are conducted in this military school are executed by Marey's method, which is capable of furnishing graphic records of respiratory movements, the pulsations of the heart and the arteries, muscular contractions, the pressure of the feet on the ground in walking, leaping, etc. The part of the body which is being examined is brought into contact with the flexible membrane of a Marey capsule, which is connected by a rubber tube to a similar capsule, whose membrane carries a stylus that presses on a cylinder covered with blackened paper and turned uniformly by clockwork.

The variations of muscular effort are registered by the well-known ergograph of Mosso.

The mechanism of bodily movements is studied also by means of photography, kinematography, and, especially, chrono-photography. The kinematographic analysis of movements enables the physical instructor to discover the physiological consequences of various exercises, and to classify the latter according to their effects, but he must control his deductions by attentive observation of the movements.

Chrono-photography may be defined as the photographic reproduction of successive positions of a moving object on a single fixed plate. Graphic chrono-photography is based on the same principle, but it furnishes a much larger number of images in a given time. The pictures of this sort that are produced at the Joinville school are exceedingly interesting, and convey very valuable information in regard to walking, high and broad jumping, and other exercises. So, at Joinville, physiologists and trainers work together for the improvement of physical education.

The Anti-trust Bills and the Patentee

PATENTEES have concerned themselves but little with the proposed anti-trust legislation which will soon be presented to Congress in the form of what is known as the Clayton Bill; yet that measure contains provisions which will profoundly affect the marketing of patented inventions and which will certainly be objected to by inventors and by manufacturers of patented articles.

Every invention, great or small, means a revolution in its way—a revolution in the way of shaving your face, if the invention be a safety razor; a revolution in house-cleaning, if the invention be a vacuum cleaner; a revolution in communication, if the invention be a duplicating machine, such as a mimeograph; and a revolution in transportation, if the invention should be an airship or a locomotive. Revolutions are not popular, particularly when they mean a change in personal habits. When one reads of the trials and tribulations of inventors, big and little, it is immediately driven home that the great conservative mass of humanity receives new ideas about as cordially as a Czar receives nihilist bombs. The new invention must be introduced very gradually; the general public must be educated to its use artfully by newspaper propaganda, public demonstrations, and much advertising. Difficult as it is to market staple products, the task of inducing the public to take an interest in a new invention is far greater.

If the Clayton Bill becomes a law—and it seems certain that some form of anti-trust legislation will be enacted before Congress adjourns—inventors will find their progress still further impeded by formidable legal obstacles. The revised Clayton Bill provides that anyone who shall lease or sell in the United States, "goods, wares, merchandise, machinery, supplies, or other commodities, or fix a price charged therefor, or discount from or rebate upon such price, on the condition or understanding that the lessee or purchaser thereof shall not use or deal in the goods, wares, merchandise, machinery supplies, or other commodities of a competitor," shall be liable to a fine of $5,000, and to imprisonment of one year. It has been the practice among patentees to divide the market into territories, and to give enterprising retailers in each territory license for that territory, it being usually stipulated by the retailer either that he shall have an exclusive license for that territory or that a similar competing article is to be sold to any other retailer in the same territory at higher prices or on less favorable terms. Without some such arrangement the retailer's competitors will all reap the fruits of his sowing, and will compete with him for the market which his own efforts have alone created. To meet this entirely fair demand of the retailer, which the bill does not seem to condemn, the manufacturer, in turn, is entitled to fair protection. Since the patentee must depend upon the retailer to create the demand for the article against the competition of rival brands, and since the manufacturer must assure the retailer, for a specified period at least, extra reward for the retailer's extra efforts in pushing the article, it seems no more than fair that the retailer shall give the patentee substantial assurance that he will exert more than ordinary effort in selling the article. So long as the retailer carries in stock a rival invention or offers both inventions to his trade, the retailer cannot push either against the other. Indeed, by offering both inventions alongside each other in the same store, the retailer actually increases the live weight of rival competition against which the manufacturer is struggling in his efforts to get a foothold in the territory. The very least that the manufacturer can ask, therefore, is that for a specified period the retailer shall concentrate his effort upon the manufacturer's own invention. Without such assurance from the retailer the manufacturer cannot in turn give any assurance to the retailer of extra reward for extra effort; and unless the manufacturer can give such assurance he cannot hope to find a market for his invention in territory already occupied by his rivals.

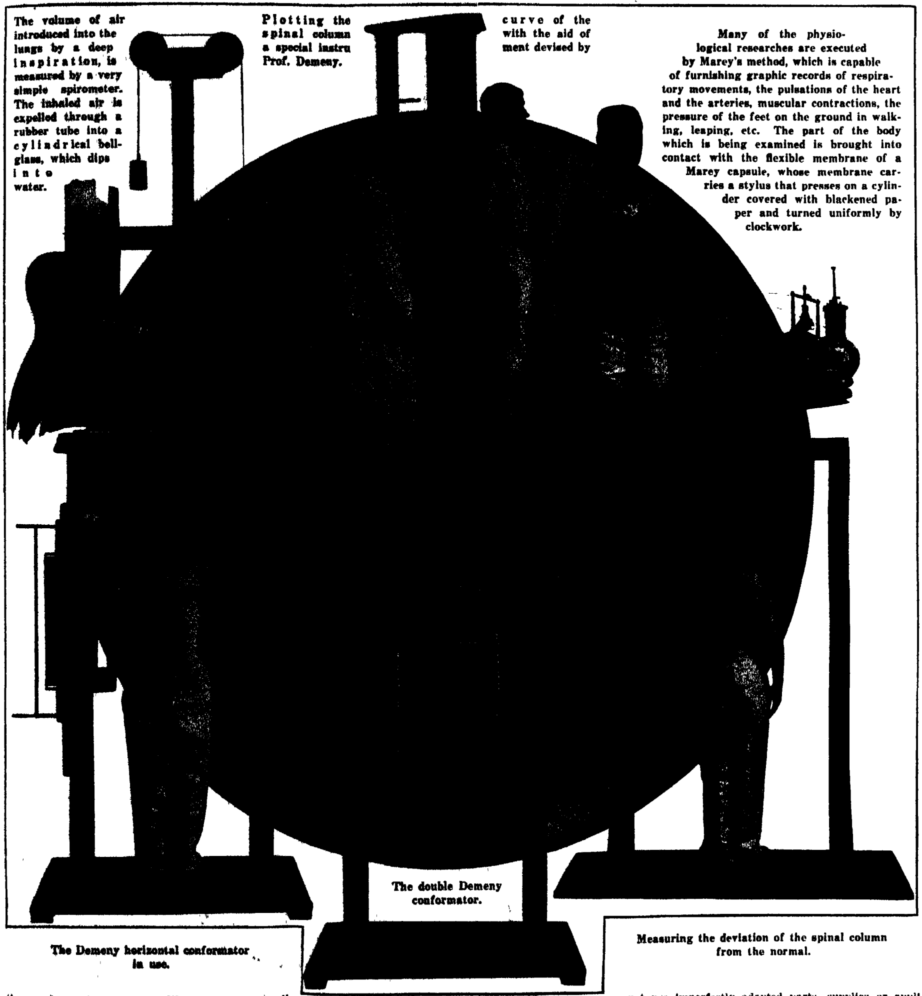
The Clayton Bill forbids the manufacturer and retailer from making any such arrangement. Any manufacturer or patentee engaged in interstate commerce becomes a criminal if he attempts to secure an ex-tire years' business as a condition of selling to a retailer; if he attempts to hold the retailer to an agreement to handle his patented articles exclusively; if he avails himself of the quality of his patented article to induce a retailer to "stock up" with that exclusively; or if he agrees in consideration of the retailer's agreement to handle his article exclusively that he will sell to other retailers only on less favorable terms.

The right to furnish repair parts—a very important right in marketing patented inventions—is affected by another provision of the bill. A manufacturer who sells a delicate machine whose successful operation depends upon perfectly adapted substitute parts, supplies, and supplementary appliances, agrees usually to furnish purchasers with such parts, supplies, and appliances, at a special price, upon the understanding that the imperfectly adapted parts, supplies or other appliances of other manufacturers shall not be used. It was brought out in the Dick case, for example, that the ink which purchasers of the mimeograph must obtain from the patentees costs no more than other ink, and that, being free from benzine, it will not dissolve the wax stencils. Other inks on the market, some of them perhaps cheaper than the ink supplied by the patentee, do contain benzine, with the result that the wax is dissolved, and that not more than two hundred or three hundred impressions can be obtained from a single wax stencil, with the result that the reputation of the machine suffers. It is possible to mention dozens of machines whose perfect operation depends upon the character of repair parts and supplies. Yet, under the Clayton Bill, a patentee may not protect the reputation of his machines by seeing that they are always operated under the best conditions.

Instead of agreeing to sell these perfectly adapted parts, supplies, and appliances at a special price, a patentee sometimes agrees to sell the original machine at a special price upon the understanding that the purchaser shall not use imperfectly adapted parts, supplies, or appliances of other manufacturers. This also is forbidden by the Clayton Bill.

But suppose a manufacturer sells no machine at all. Suppose that he only leases it, because he may be compelled to do so. The excavating machinery with which the Chicago Drainage Canal was built is an example in point. The machines in question cost $25,000 each, and there were probably not more than a dozen contractors in the whole United States who could afford to buy them. Realizing this, the manufacturers leased the machines under such favorable conditions that it was possible for any contractor to utilize them. As a result the Chicago Drainage Canal was dug at the unprecedented rate of 57 cents per cubic yard, instead of the usual 80 cents for rock excavation. The machines in question were leased on condition that certain supplies necessary for the perfect operation of the machines were to be obtained from the manufacturer. All this is forbidden by the Clayton Bill. Nor may the patentee seek to overcome the restriction by leasing the machines at a special rental upon the understanding that the lessees shall not use imperfectly adapted parts, supplies, or appliances of other manufacturers; nor may he agree to sell to the lessee perfectly adapted parts, supplies, or appliances upon the understanding that the lessee shall not use imperfectly adapted parts, supplies or appliances of other manufacturers.

Where is the stimulus to spend hundreds of thousands of dollars in devising new labor-saving machinery if this bill becomes a law? How will it be possible for a poor inventor with a good idea to interest a capitalist in his patent, if the capitalist finds it utterly impossible to market the invention in the most efficient way? Why must a man pay a fine of $5,000 and be subjected to a year's imprisonment like a common criminal because he follows business practices which good morals and honorable business conduct have sanctioned from time immemorial?



The volume of air introduced into the lungs by a deep inspiration, is measured by a very simple spirometer. The inhaled air is expelled through a rubber tube into a cylindrical bell-glass, which dips into water.

Plotting the curve of the spinal column with the aid of a special instrument devised by Prof. Demeny.

Many of the physiological researches are executed by Marey's method, which is capable of furnishing graphic records of respiratory movements, the pulsations of the heart and the arteries, muscular contractions, the pressure of the feet on the ground in walking, leaping, etc. The part of the body which is being examined is brought into contact with the flexible membrane of a Marey capsule, whose membrane carries a stylus that presses on a cylinder covered with blackened paper and turned uniformly by clockwork.

The Vertical Distribution of Animals

THE accompanying drawing, reproduced from the *Illustrated London News*, shows the vertical distribution of animals in the five continents. The distance between the horizontal broken lines represents 3,000 feet. The highest point at which any animal occurs is shown by a black solid line beside the animal. The altitudinal range of the animals may extend in many cases as far down as sea level, and no animal is confined to the altitude at which it is drawn, but will extend some thousand feet lower than where actually placed.

The chief factors in the distribution of animals are suitable climate or temperature, and a suitable food supply. The food supply is obviously correlated with the temperature. In general, it may be said that the vertical or altitudinal distribution of life corresponds closely with the latitudinal or its distribution north and south of the equator. At high altitudes the temperature is cold, and we frequently find there the same type of animal that occurs at sea level in Arctic regions. Thus, essentially the same type of hare at 12,000 feet in the Alps will be found at sea level in northern Norway and Sweden. The llama, occurring at over 15,000 feet in the tropical Andes, is found at sea level in Patagonia.

The upper limit of animal life virtually corresponds with the lower limit of perpetual snow, and animals are much more abundant at lower levels, because of increased warmth and food supply. The upper part of the picture (Alps, Caucasus) represents Europe, all in the temperate zone, and shows the lower level of perpetual snow between 12,000 and 15,000 feet; while the lower portion of the picture shows the snow line at over 18,000 feet, due to the continents of Asia, Africa, and the two Americas lying partly in the torrid zone. Note that the chamois of the Caucasus is found at a slightly higher altitude than the chamois of the somewhat more northerly Alps. In Europe the woodcock is found as high as 7,500 feet, but in Asia it ranges up to 18,000 feet.

The most conspicuous mammal found at greatest height is the yak of Central Asia, attaining 19,000 feet and never occurring lower than 10,000. This is much exceeded in actual height by American vultures at 24,000. These, however, do not dwell at that altitude, but only attain it at times in their flight, obtaining their food and rearing their young at lower levels. Reptiles occur at relatively low levels, as shown by the viper (Caucasus, 8,000 feet). Insects for the most part prefer lower levels and warm climates, but may occur at high altitudes (spiders, beetles; Alps, 16,000 feet).

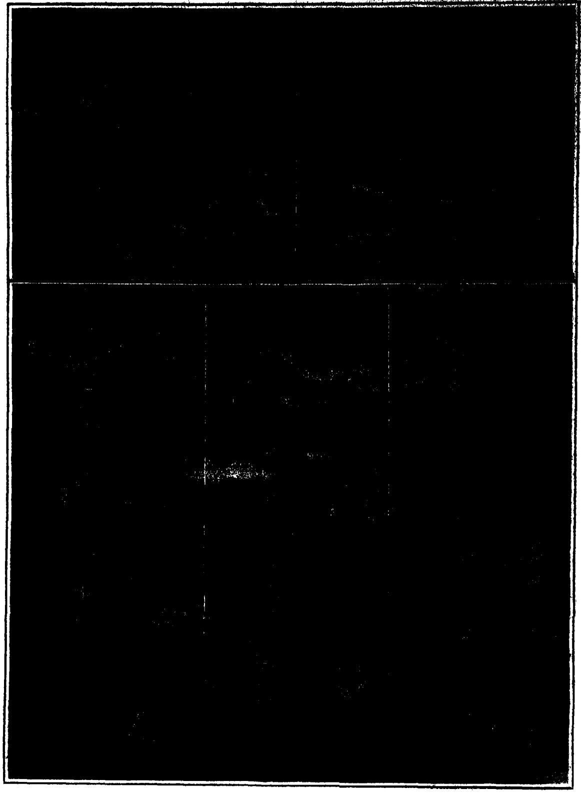
The extensive altitudinal range of certain animals or groups of animals is well shown in the section across South and North America; humming birds, from over 16,000 feet to sea level; armadillos, from 18,000 feet in the Andes to sea level in Brazil; deer, from 15,000 feet in tropical America to sea level in temperate and Arctic portions; bears, from the spectacled bear at nearly 16,000 feet in Ecuador and the true bears from 9,000 feet to sea level in temperate North America to the polar bear of the Arctic, never found more than a few feet above the ice of the ocean.

The high altitude attained by some animals is quite surprising. Note the African elephant at nearly 15,000 feet against the Indian elephant at scarcely over 6,000 feet, and observe where each would come if placed at similar heights in Europe. The high altitudes of certain [illegible] inter- [illegible] and [illegible] al- [illegible] and [illegible] essentially tropical animals, as shown by the [illegible] and lemurs, all under 3,000 feet. Sloth and anteater are also tropical animals, one reaching [illegible] and the other just over [illegible] feet in the new world tropics. The lion is more tropical than the tiger, being found at about 4,500 feet, while the latter ranges over twice as high, and is found near sea level in Siberia. The tse-tse fly is also tropical, occurring no higher than 4,500 feet in torrid Africa, so that one could dwell in Africa at over 5,000 feet and be safe from its ravages.

The peculiar animals of the Australian region, not found anywhere else, dasyures, wombats, kangaroos, wallabys, lyre-birds, and kiwis, etc., are tropical or temperate in nature and occur at relatively low altitudes, all under 6,000 feet. There are few high mountains in the region inhabited by them.

One important fact in the altitudinal distribution of life not shown in the drawing is that on mountains, the southern slopes exposed to the sun's rays are much warmer than the northern, so that animals are found at much higher altitudes on them than on the colder northern slopes of the same mountain. Also animals have a tendency to range higher in summer than in winter in the northern hemisphere, and of course the reverse in the southern hemisphere.

A knowledge of the vertical distribution of animals in any particular portion of the world is of value to man in indicating the climate of a region, of suitable crops for cultivation in such area, and of suitable breeds of animals to rear, and also in the selection of health resorts. There are parts of tropical Asia, Africa, and America, which to all intents and purposes belong to the Arctic or to the temperate zones, depending upon the elevation, and each is occupied for the most part by an appropriate assemblage of boreal or of temperate animals and plants.



This drawing, reproduced by courtesy of the "Illustrated London News," is designed to show the vertical distribution of animal life.

It is based on a series of maps which illustrate the distribution of over seven hundred families, genera and species of existing animals, and which constitutes volume 5 of Bartholomew's Physical Atlas, published at the Edinburgh Geographical Institute by John Bartholomew & Co., under the patronage of the Royal Geographical Society. While the drawing shows the highest point at which any particular animal is to be found, it does not indicate the range of that animal. The space between each pair of dotted lines represents three thousand feet.

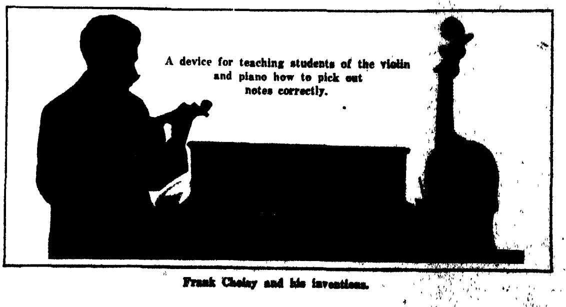
Some Helps for the Music Teacher

By Dr. Alfred Gradenwitz

IN the case of the piano, the sound corresponding to each note is invariably fixed on the instrument. Only a mistake in the key to be struck may result in grave disharmony. On the violin, and for that matter, on all string instruments, the pitch of each sound, however, depends on the position of the pupil's fingers, and since this in the beginning is practically never correct, no strictly correct sounds can be expected.

A distinguished violin teacher and composer, M. Frank Choisy of Geneva, Switzerland, has devised a simple attachment destined to obviate this drawback. The "joujusta," as this is called, is a mere sheet of paper on which the notes are inscribed

(Continued on page [illegible])



A device for teaching students of the violin and piano how to pick out notes correctly.

Frank Choisy and his inventions.

Aeroplane Bomb in Morocco

THE Spanish army in Morocco has found the aeroplane a very effective means of coping with the guerrilla warfare of the natives. Two men in an aeroplane can sweep a wide area of difficult country and clear it of small bands or solitary snipers by dropping explosives upon them from a height above the effective range of their rifles. Needless to say, three dimensional warfare is not to the liking of the Moor. The sight of an aeroplane is in itself terrifying enough to the superstitious native. The accompanying photograph shows one of the Spanish military biplanes and the bombs that are thrown from it. By this means operations have been carried on against the Moors in regions where, hitherto, they have been safe from attack.

An Attachment for Talking Machines and Gramophones Which Improves Their Reproduction

IN the SCIENTIFIC AMERICAN of September 27th, 1913, we published an article on an invention patented by Mr. M. B. Claussen for amplifying the reproductions of talking machine records, which invention consisted in inserting the steel reproducing needle through a specially formed celluloid disk. Simple as the invention is, the effect is remarkable. With a fine needle a volume of sound can be obtained which exceeds that produced by a coarse needle, with the additional result that all the delicate shades which only a fine needle can reproduce and which escape a coarse needle, are heard. Mr. Claussen has patented a modification which permits the use of the fiber needle. If anything, the effect of the celluloid disk is even more pronounced than with the steel needle. Those who use fiber needles know that they are superior to steel points because the scratching is reduced, the tone is purer, and the records are not worn away so quickly. Mr. Claussen passes the fiber needle through a ball and socket joint in the center of the disk, so the needle can be adjusted to any angle. It is now possible with this invention to use the fiber needle with those records for which it is peculiarly adapted, with the assurance that the sound to be obtained is greatly amplified and a richness of quality obtained otherwise quite impossible.

The Kufas of the Tigris

HERODOTUS, in the account of his travels, made note of the peculiar boats used on the Euphrates, as follows:

"The boats used by those who come to the city of Babylon are of a circular form, and made of skins. The ribs of the vessels are formed of willow boughs and branches. They are round like a shield, there being no distinction between the head and the stern. They line the bottoms of the boats with reeds. The boats have two oars, one man to each. One pulls to him; one pushes from him."

Very evidently that is a land of little progress; for circular boats are still to be found there, which fit exactly the specifications jotted down by the Greek historian. They are known as "kufas" and are in common use on the Tigris. The photograph shows a typical scene at Bagdad. The buoyancy and stability of the kufa is demonstrated by the boat in the foreground, which is about to land its passengers.

Old circular boats used on the Tigris.

Curious Life-saving Suit

A GERMAN engineer has invented a very peculiar life-saving device, which is illustrated in the accompanying engraving. It consists of a water-tight canvas suit in the shape of a bag, with sleeves for the arms and a dome-shaped top that closes over the wearer's head. The sleeves terminate in gloves, so that no water can enter the suit through them. The top is provided with a porthole, through which the wearer may take note of his surroundings. However, a slide is provided to seal the porthole hermetically. Projecting from the top of the suit is a pipe through which air is admitted. In order to keep the device upright, a metal can or bucket is fastened to the bottom of the suit. There are openings in the top of the bucket, so that it will fill with water and act as a weight. Within the suit a limited stock of provisions may be carried. Around the top hand ropes are secured, to which two or three persons may cling and keep themselves afloat. The occupant of the life-saving device can propel himself by using his arms as paddles.

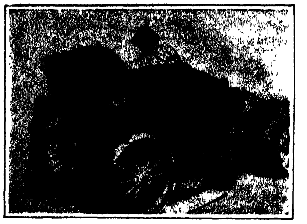
Motor Stage Line Over a Desert

THE lapse of ten or, at the outside, not more than twenty progressive years has driven the far-famed stage coach from the highways of the West. To-day, where the railroads have not penetrated the motor stage holds undisputed sway.

There is an automobile stage running between Yuma, Ariz., and Holtville, Cal., which is truly a curiosity. Holtville lies at the eastern edge of the developed portion of the Imperial Valley. From there it is a jump of 56 miles across the desert to Yuma, Ariz. There is a railroad running from Yuma to Holtville, but it goes by a circuitous route, and costs the traveler much money and time. Accordingly, an enterprising man, George H. Johnson, undertook to establish a motor stage service. Before the loaded car had gone ten miles on its first trip, it was wallowing up to the axles in the sand of the Colorado River desert. After shoveling it out, Johnson spread long strips of canvas ahead of the machine, and in that way kept it out of the sand-holes to the end of the journey. But that was too slow a method of traveling. Service was discontinued until the problem was solved.

Johnson invented what we might call a "sand belt" to keep the machine from sinking into the sand, while it is crossing the desert. It is merely a set of threshing machine belts so arranged upon wood rollers that they travel over and under the rear wheels of the car, much in the same manner that the caterpillar engine's track rolls along beneath it when it is in motion. The belt is about a foot wide, and it runs upon a roller over each wheel, and another roller located about midway between each front and rear wheel. The belt is about half an inch thick, and it runs rather slack. It is easily attached and removed, and is substantial enough to hold the rear wheels out of the sand when it is crossing the desert with a load of passengers.



Sand belts to keep the wheels of the car from sinking into the sand.

How a Serious Accident May Be Prevented

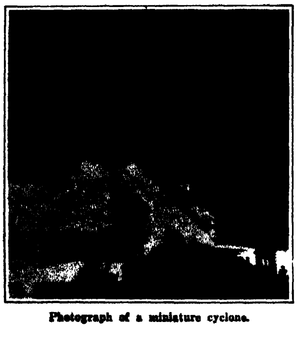
A SERIOUS accident can happen with an automobile in case the driver stops it by simply cutting the ignition and braking, without putting the speed lever at the off point, for should the motor clutch remain on, the car will start off as soon as the crank is used to set the motor running The driver thus risks being run over by his own car, or the vehicle runs wild at a high speed. An ingenious electric device can be used to make such an accident impossible, and it consists in mounting a relay so that when its magnets work, the relay contact cuts the ignition circuit. The magnet is in a battery circuit, which includes the crank, motor, and speed lever The sector of the speed lever is specially made so that all the points except the zero point make connection with the circuit, while the zero point cuts the circuit. When the lever is on point 2, for instance, current can pass through the lever part to the magnet. Suppose the lever to have been left by mistake on this point, when the driver applies the crank against the motor for starting, he closes the circuit and operates the relay, thus opening the second or ignition circuit, which as stated is worked by the relay contact. Applying the crank thus cuts the ignition and it is impossible to start the motor until the lever has been shifted to the zero point on the sector

Another Russian Gold Field

THE American consul general at Moscow reports that rich gold fields have been found in the district of Anadyr, Siberia, along the River Bielaya, consisting of a thick stratum of auriferous sand under a thin layer of peat. The difficulty of mining is great, owing to the fact that food and other necessaries cannot be procured nearer than at a distance of 200 to 300 miles

Miniature Cyclone

THE freak cloud herewith illustrated was photographed at Whittier, Cal., following a heavy rainstorm. The cloud was very active, having a rapid spiral movement, at the same time traversing the sky with the group of clouds to which it seemed attached. It remained visible for perhaps an hour, but was ultimately broken up, apparently by its own violent movement.



Photograph of a miniature cyclone.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

LIFE SAVING SUIT—CARL G. WALLS, 33 Tompkins Place, Brooklyn, N Y. This life-saving suit is designed to keep the wearer afloat in the water, while at the same time allowing convenient use of arms and legs for swimming and other purposes The suit which is waterproof and air tight is not only adapted for victims of accidents at sea, but also for hunters, fishermen and soldiers, in short for every one exposed to cold and dampness.

LIFE-SAVING SUIT.

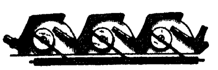
Of Interest to Farmers.

BEET-HARVESTER.—J. B. DAWSON, Box 57, Pompeys Pillar, Montana. This harvester is adapted for use with crowning mechanism previously patented by Mr. Dawson, but may be used with any other form of crowning mechanism. Means are provided for lifting the crowned beets from the soil without injury, separating them from the soil, and delivering them into a dumping container

TRIP MECHANISM FOR BUNDLE-CARRIERS.—J BAXTER, R. F D. No 3, Moscow, Idaho. To provide means for stopping the delivery of bundles or sheaves from a carrier, to provide means for manually releasing the bundles for delivery, and to simplify the mechanism for effecting these operations, are the principal objects of Mr Baxter's invention.

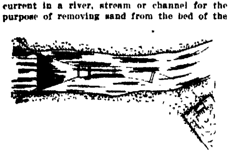
Of General Interest.

GRATING.—A. DARROCH, 369 Ninth St, Brooklyn, N Y. This inventor's object is to provide a grating for use in roofs of subways, buildings and other structures, and arranged to prevent rain water, débris and the like from passing through the grating, to illuminate the space below the grating by refracted light, to provide proper ventilation for the said space, and to close the grating in case of fire to prevent draft To accomplish this result, use is made of grate bars provided with arched roofs open at one side a building light extending under each roof below the opening thereof, and a ventilator under each roof adjacent the inner end of the said building light



GRATING FOR SUBWAYS, BUILDINGS, ETC.

SAND AND WATER CONVEYER.—C A DEAL, 4209 Walnut St., Kansas City, Mo. This improvement relates to means for utilizing the current in a river, stream or channel for the purpose of removing sand from the bed of the body of water and conveying it from a point up-stream to a point far enough down-stream to allow sufficient fall for the purpose

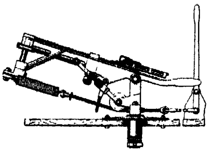


SAND AND WATER CONVEYER.

SPARK ARRESTER.—S E PHEISTER, Yacolt, Wash. This improvement relates to a spark arrester to be applied to the smoke-stack of locomotives, stationary boilers, and donkey engines and other similar engines, and arranged to permit of the free escape of the smoke, while arresting the cinders, sparks, etc.

WINDOW-FITTING FOR BLINDS—F F COWDROY, 311 Miller Street, North Sydney, New South Wales, Australia. To eliminate the damaging effects of repeatedly fixing brackets to window frames for shades of different width, Mr Cowdroy has invented a fixture which may be permanently attached to the window and which has shade brackets adjustable laterally for various sizes of shades, and curtain pole brackets adjustable vertically for curtains of different lengths.

BLUE ROCK TRAP.—D. BEST, San Leandro, Cal. An object here is to provide a device having a frame which may be turned at any angle of the field, without causing extra strain, or having a tendency to pull the frame out of position. A further object of the invention is to provide a device in which the rocks are caused to spin, and in which the throwing arm is automatically brought back into position ready for another throw.



BLUE ROCK TRAP.

AUTOMATIC DRAIN VALVE—W R HUDDLESTON, Box 174, Brownsville, Tex The purpose here is to provide a valve adapted for use in connection with the main reservoir of air braking systems, for automatically draining the reservoir and the system of water wherein a normally open spring supported valve is provided, adapted to be closed by the pressure in the system, when such pressure exceeds the normal atmospheric pressure.

AUTOMATIC DRAIN VALVE

Hardware and Tools.

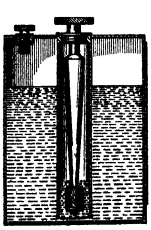
NUT LOCK.—A H. WEGENER, 1105 Garden St., Hoboken, N. J. Among the objects of the invention is to provide an automatically gripping device for locking a nut to a bolt, but which will permit the unscrewing of the nut under force applied thereto by means of a wrench or the like without seriously damaging either nut or bolt thread.

FASTENING DEVICE—M J. MYERS, care M. J Myers Co., 135 W. 26th St., New York N. Y. The inventor provides a device which may be used on clothing and other articles, and which is constructed by providing a member with a longitudinally extending slot terminating at its ends in stud openings one of which extends in the member at one side of the slot, and the other extends in the member at the other side of the slot

SNAP HOOK.—C. E. KELLY, Griffin Corners, N Y. With the present invention Mr Kelly provides the catch with guiding means to control the same when it is moved into and out of locking position, and he secures the spring in fixed relation to the catch, so as to make the hook more easily operable

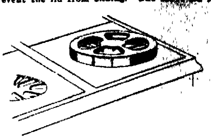
Heating and Lighting.

PORTABLE LIGHTER—G SCHLEICHER, 37 W 14th St, Manhattan, N. Y, N. Y Among the principal objects which the present invention has in view are to provide a container to hold free liquid fuel for use in delivery in regulated quantities, to avoid flooding and evaporation of the said fuel; and to prevent a variation in the delivery of the fuel from the said container In the accompanying engraving a vertical longitudinal section of the portable lighter is shown.



PORTABLE LIGHTER.

STOVE-LID.—J. BRAUBACH, 107 Fourth St., Hoboken, New Jersey. The lid is adapted to be used on gas stoves of usual construction, being provided with shoulders adjusted so at the sides of the opening in the stove top to prevent the lid from sliding. The [illegible] is provided with a centrally disposed disk with a series of holes clustered about it and a series of strengthening webs all with the purpose of diffusing under control the heat produced by the gas burner.



HEAT DIFFUSING LID FOR GAS STOVES.

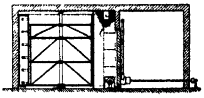
Household Utilities.

SAD-IRON.—J. W. AUSTIN, care of Central Flatiron Manufacturing Company, Binghamton, New York. This sad-iron is provided with means whereby the size of the mixing chamber for the gas and air can be enlarged or reduced at the will of the operator. The burning gas is utilized to the best advantage and all danger by back-firing is completely prevented, the usual chimney being dispensed with.

ATTACHMENT FOR COOKING UTENSILS.—C. N. SOWDEN, Guantanamo, Cuba. The invention provides a means for holding two sauce-pans or like utensils of different size, relatively spaced one within the other so as to constitute a double cooker. The attachment consists of a device which may be applied to the handles of the two utensils to hold them in the proper fixed relation to each other.

Machines and Mechanical Devices.

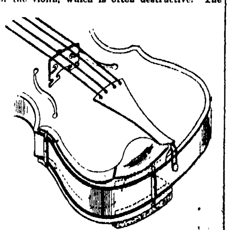
REFRIGERATING APPARATUS.—S. MACKIN, 1020 Santa Rita Ave., Laredo, Tex. The main object of the invention is to provide a means for hardening ice cream. The apparatus is provided with a series of shelves which may be revolved to bring them in position whereby the contents of the shelves may be removed or replaced. The shelves are placed in a novel form of vault and novel means for maintaining the vault in cold condition are provided



REFRIGERATING VAULT FOR HARDENING ICE CREAM

Musical Instruments.

VIOLIN CHIN REST.—C. J. EDLAVITCH, 12 Albemarle St., Baltimore, Md By the use of widely spaced clamping members, this invention avoids creating a strain at a single point of the violin, which is often destructive. The inner portion of the chin and shoulder plates are prevented from coming into contact with the surface of the instrument Such contact would destroy, in a measure, the tone of the instrument.



CHIN REST THAT AVOIDS STRAINING VIOLIN BODY.

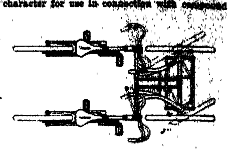
Prime Movers and Their Accessories.

MEANS FOR PROPELLING SHIPS AND THE LIKE S. GOUNOUILHOU, 8 Rue de Cheverus, Bordeaux, France. This invention has for its object a system of propulsion for ships and the like by means of wheels, and has more particularly for its object to direct the fluid jets projected by the wheels in such a manner as to bring them into a horizontal direction and utilize their *vis viva* for the propulsion.

ROTARY EXPLOSIVE-ENGINE.—J. D. BLAYNEY, Edmonton, Alberta, Canada. The apparatus consists of a series of explosive engines grouped about a central driving shaft. Each engine drives a pinion meshing with a large gear upon the driving shaft, the object being to obtain greater [illegible] size and weight, and [illegible] of equal distribution of [illegible] and proper balancing of the parts.

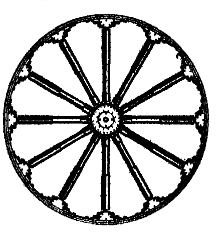
Pertaining to Vehicles.

STEERING GEAR FOR VEHICLES.—[illegible] OTTEN, 1862 Linden St., [illegible] N. Y. This invention relates to steering gears for vehicles and has particular reference to means of this character for use in connection with compound cycles or devices which are propelled by the riders or by motive power. More particularly stated the invention contemplates the employment of two bicycle constructions made or connected in parallel and with a single steering mechanism for the combined wheel.



STEERING GEAR FOR VEHICLES.

RESILIENT WHEEL.—A. T. GOOKIN, 50 Dana St., Cambridge, Mass. This improvement involves a new form of resilient wheel, and the principal purpose of the invention is to provide an improved device of this class. A further object is the provision of a wheel made up of a hub and rim with a number of resilient spokes therebetween, whereby when the wheel rolls over the ground the resiliency of the wheel will take up the shocks due to unevenness of the road.



RESILIENT WHEEL.

DOOR-LOCK.—W. J. FLEISCHAUER and H. RICHARDSON, 10 Edison St., Pontiac, Michigan. The invention provides an improved lock of the type particularly adapted for use on automobile doors. It consists of a strong and durable construction embodying a minimum number of parts so co-operating as to prevent the door from rattling when closed.

WATER, LAND, AND AIR MACHINE.—E. E. GREGORY, Central City, Ky. The invention provides a hydro-aeroplane adapted to run on land. Hence, this vehicle may be used as an aeroplane, as a boat or as a land vehicle, without any change in device when going from one element to the other. The vehicle is provided with a novel form of hull for use on the water which serves as a main sustaining plane when used in the air.

Designs.

PAPER BELL.—B. KARFIOL, care of Royal Wastepaper Works, 842 Lorimer St., Brooklyn, N. Y. The bell is of the folding paper type, and has parallel horizontal stripes of various solid colors extending through it.

WEDDING RING—M. ROSEN, 1167 Vyse Avenue, New York. A distinctive characteristic of this design is that annular spaces of even width extend about the ring to show both at the outer and inner surfaces thereof.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

"SIXES" RUN 32.8 MILES ON ONE GALLON OF GASOLINE

NINETY-FOUR CARS MAKE STARTLING AVERAGE IN "FRANKLIN" TEST

"Stock" Machines With Three Passengers Each Make Simultaneous Record Runs in All Parts of United States

VICTORY FOR LIGHT-WEIGHT IDEA

Many Dealers, Sold Out, Compelled to Borrow the Machines of Local Owners to Take Part. Varying Weather Conditions Met.

Syracuse, N. Y.—On May 1st, 94 Franklin dealers in the United States and Canada, in 94 Franklin Six-Thirty stock touring cars, regardless of weather conditions, made a test to demonstrate the best possible mileage on 1 gallon of gasoline.

The rules required that the finish be as near the starting point as possible. Each test was made with two official observers, and results sworn to before a Notary Public. The test represents the average of 94 cars, 94 drivers, various road conditions, all kinds of weather, different grades of gasoline and, therefore, what can be obtained by skillful driving in the scientifically light-weight six-cylinder Franklin car.

The highest mileage, 51.2 miles, was made by Wm. F. Sanger, Milwaukee, Wis.

The different conditions under which the tests were made are graphically shown by the following telegrams:

Salt Lake City, Utah—"40.1 miles. High wind and wet roads or could easily have made 50."

Laramie, Wyo.—"32.1 miles. Weather cold. Roads rough but hard."

San Diego, Cal.—"33.1 miles. Roads very slippery. Drizzling rain during run. Rather cold. Conniry drove. Top and glass front down. H. C. Covell, Club Representative; Louis Elmgren, Fire Chief; observers. Car with load weighed 3385."

Georgetown, Texas—"Made 17.2 miles. Top and windshield up. Wet and badly washed pike roads. Very little wind. Three passengers and car weighed 3310 including accumulated mud. Showered just before starting. Average speed eighteen miles per hour. Affidavit follows by letter."

Bangor, Maine—"21.5 miles. Dry dirt roads, rough in places, and hilly. Weather cold, thermometer 31 at six, 45 at end of run. Strong wind. Driver Hall. Weight 3250. Glass front and top down. Snowed lightly during night. Started at ten, finished at eleven-thirty."

Newark, N. J.—"On official test obtained 34-4/10 miles. Roads dry, fair condition. Weather clear, mild. Driver Walter Parcells. Weight of car including passengers 3320 pounds. We doubled back over identical course. Course contained 15 hills (grades from 2 to 8 or 10 per cent). Demonstrating car used, run total 5,000 miles covered period 6 months."

York, Pa.—"Made thirty-seven and nine-tenths miles on turnpike which was covered one tenth of way by deep blue stone. Can do forty-five miles if roads are in good condition."

Kansas City, Mo.—"Williams makes forty-two and eighty-eight hundredths miles on one gallon gasoline. Weather cool. Slight wind. Roads good."

(Continued in booklet, sent free on request by Franklin Automobile Company, Syracuse, N. Y.)

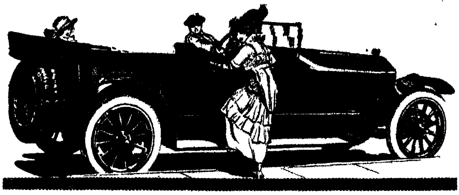
FRANKLIN SIX-THIRTY, 2725 POUNDS, 4½ INCH TIRES



National

Beauty, Luxury and Utility That Reflect Good Taste and Judgment

The smart, sloping hood and pointed effect of the *National* (due to the body converging towards the radiator) adds a distinct note of attractiveness. The wide metal guards are enclosed, continuous and unobstructed. These points of refinement and care help give the *National* its *ensemble effect* of a long, low, graceful craft.

The admitted mechanical superiority of the *National*, added to its comfort and convenience, gives you the ideal combination of a quality car, built and guaranteed by an old, reliable and successful institution. The rear springs on the new "SIX" are of the Cantilever type. The left side drive, center control, convenient and simple dash equipment and easy access to all four doors add to your comfort and satisfaction.

National cars are built for service, proved by their fourteen years of dependability and reliable performance; their ample reserve force and speed when you need it, or two miles an hour if you prefer.

We say "you don't have to raise the hood" because the *National's* success justifies your confidence in our mechanical ability.

If All Tires Were

PENNSYLVANIA
Oilproof
VACUUM CUP TIRES

Skidding on slippery pavements—the greatest single cause of automobile accidents—would be unknown.

V. C. tires have been guaranteed for many years not to skid on wet or greasy pavements, else returnable at purchase price. Never a claim from a user.

Tire trouble and expense—the greatest drawbacks to the use of automobiles—would be so normal and nominal as to constitute the least of all automobile service complaints.

V. C. tires are guaranteed for a low minimum of 4,500 actual miles and maintain an average nearer twice that distance.

The oiled road would be a *complete* comfort—not to be avoided but enjoyed.

V. C. tires are guaranteed absolutely immune to the rubber destroying effects of oil.

Every year adds enormously to the number of those who know Vacuum Cup Tires as the ONLY tires for utmost safety and service. 1914 has already broken previous yearly records.

Training Marksmen by the Kinetomatograph

(Concluded from page [illegible].)

light was shining, becomes shifted a quarter of an inch, and is thus obliterated, the screen presenting an opaque surface to the firing line once more. By moving the back or third sheet at intervals in a horizontal direction the possibility of a series of holes—one in each sheet—coming into line and indicating a false hit is rendered extremely remote.

When the rollers have become exhausted of paper it is only necessary to change them, thereby permitting the paper to be used again. As a rule the picture is kept stationary upon the screen for about two seconds, which is quite adequate for determining the effect of the shot.

The pictures are projected at the normal speed—16 per second—and at first sight it may be thought that the almost brutal instantaneous starting and stopping of the projector mechanism would injure the film. But such is not the case. The wear and tear upon the celluloid ribbon is no more severe than when it is run through the lantern in the usual manner.

Holding the picture stationary in the gate under full illumination, however, presented one difficulty. As a rule, if a film is arrested and held for only a fraction of a second it will ignite, owing to the intensely concentrated heat brought to bear upon it. Although ordinary films are used in this apparatus there is no risk of firing. A radiator is built around the condenser, which acts as a cooling tank, and this keeps the celluloid film quite cool during the period of rest.

The great advantage accruing from this "life target," as it is called rather appropriately, is the way in which it fosters quick sighting and snap shooting. This is the factor which appeals especially to military experts to-day. The recruit may be somewhat slow in these elements when he faces the target for the first time, and even twelve pictures per second is somewhat too rapid movement for him, but he soon realizes the new conditions and almost mechanically adapts himself to the life-like conditions. Within a few weeks he becomes as efficient a snap-shooter and marksman as could be desired and far more so than is possible by ordinary target practice

Possibly the one objection to the system is that the range is point blank. It can be used only for short distances. The average firing distance is about 30 feet, which, with the modern service weapon, is too short to be likely of realization in actual service. This limitation arises from two sources. The first is the restricted widths in which the paper can be woven at the mill, as a big screen formed by attaching two or three widths together is impracticable, owing to the risk of light showing through immaturely prepared seams, and from mechanical difficulties attending the utilization of reels of paper say twenty feet wide. The second is an optical problem Under present conditions 300 feet represents approximately the extreme distance at which a picture thrown upon a screen may be seen clearly. Consequently, when it comes to service practice with a magazine rifle, questions of trajectory and windage do not arise. This drawback, however, is of secondary importance in one respect, since practice with the target assures that desideratum which is essential to modern military conditions—to sight and fire quickly.

Some Helps for the Music Teacher

(Concluded from page 432.)

at the place corresponding with each of them on the four strings of the instrument. This sheet, which is made in various sizes, is slipped below the strings and fastened to the handle by moistening its gummed edges. The pupil has only to put the fingers of his left hand on the black dots corresponding to the notes, in order to produce every sound with absolute purity. At the beginning of instruction, this gymnastics of the fingers should preferably be made without bow, the latter being at first put empty on the strings.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

AGENCIES WANTED

OLD ESTABLISHED London Firm seeks agencies for Patented articles and novelties, or representation of American Firms of good standing. Rickmann Limited, Huggin Lane, Queen Victoria St., London, England.

HELP WANTED

Young men of good personality and education, possessing tact and ability for special work in connection with our Circulation Dept. To those who fill our requirements we can offer pleasant, remunerative employment either for part or the whole of their time. Apply by letter only to Circulation Dept., Scientific American, 361 Broadway, N. Y. City

POSITION WANTED

AN EXPERIENCED TEACHER of Technical English wishes a permanent position in connection with a first-class Engineering or Mining School. Excellent references. Teacher, Box 773, New York.

SCIENTIFIC APPARATUS

GLASS APPARATUS, thermometers for scientific and industrial laboratories, surgical glassware, experimental work. For further particulars address Laboratory Supply Co., 126 State St., Rochester N.Y.

SPECIAL MACHINERY

EXPERIMENTAL WORK. Special Machines. Let me build your model, develop or manufacture for you. First-class machine-shop at your service on hourly or contract basis. For particulars apply to A. H. Emery, Glenbrook, Conn.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry may be repeated.

Munn & Co., Inc.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut and granulate leather.

Inquiry No. 9359. Wanted the name and address of a firm that makes razor blades for all makes of safety razors.

Inquiry No. 9360 Wanted the name and address of parties making pipe fittings such as ferrules, stems and bowls such as could be used in the making up of calabash pipes for smoking.

Inquiry No. 9361. Wanted to buy a Nut Cracking Machine, especially good for Pecans.

Inquiry No. 9362 Wanted the name and address of the makers of a machine for splicing ties.

Inquiry No. 9363. Wanted the names and addresses of manufacturers of machinery for printing on intaglio copper plates.

Inquiry No. 9364. Wanted the name and address of buyer of mica in a crude state.

Inquiry No. 9365. Wanted the name and address of a manufacturer of machinery for embossing tin foil as is used in packing cigarettes.

Inquiry No. 9366. Wanted the name and address of a manufacturer of wire wheels, front axles complete with steering or separate, light sheet metal bodies, fuel tanks with cocks, pressed steel frames, mufflers, motors of the two-cylinder opposed type, cushions and many smaller parts for cycle cars.

Inquiry No. 9367. Wanted the name and address of a manufacturer of an automatic [illegible] machine.

Inquiry No. 9368. Wanted, the name and address of glass-bottle manufacturers or glass blowers who can manufacture a glass bottle and perforate it with some 12 small holes, in large quantities for export, to sell at a popular price.

Inquiry No. 9369. Wanted, the names and addresses of users of Indian Steatite (Soapstone), Corundum and other Indian minerals, in quantities.

Inquiry No. 9370. Wanted the names and addresses of manufacturers of small wooden articles, particularly in such soft woods as pine and fir, for articles such as toys, furniture, etc.

Inquiry No. 9371. Information wanted where one could buy or have made to order machines to be used for making solid back brushes.

Inquiry No. 9372. Wanted the name and address of manufacturers of a collapsible box about 12 inches square. It must be strongly made to withstand rough usage in transit.

Inquiry No. 9373. Wanted the name and address of a manufacturer of machinery that will make twine out of scrap paper.

Inquiry No. 9374. Wanted the name and address of manufacturers of a powder which, when mixed with cold water, will make a white paste suitable for papering, costing no more than 3 cents per pound in ton lots.

Inquiry No. 9375. Wanted the name and address of the manufacturer of a [illegible], invented especially for shoes and other [illegible].

Used by most manual training schools.

PIKE PEERLESS TOOL GRINDER

The Pike Patented Bevel Guide enables anyone to grind an edge true—and do it in record time, without drawing the temper or "burning" the steel.

Guaranteed Forever against all mechanical defects. Pike Peerless Junior, $5. Pike Peerless Senior, $7. Foot Power $1.50 extra. Other Pike grinders from $3 up at your hardware or tool dealer's. Under Pike trademark you can also get the best stone for every other sharpening need—for home as well as shop. Ask to see a Pike Kantbreak Knife Sharpener, a Pike Scythe Stone or a Pike India Oilstone (fastest cutting, longest lasting). All guaranteed. "PICK A PIKE."

FREE A Pike India Stone. Send 4c to cover packing and mailing and get a handy Pike India Vest Pocket Stone free—great for penknives, etc. Mention dealer's name and we'll also send "How to Sharpen," best book ever written on the subject. You'll be pleased. Write today.

PERPLEX
Prism Binoculars

are a revelation to any one who travels, camps, hunts or gets "out-of-doors."

New York, April 14, 1914.

Amer. Thermo Ware Co.

Gentlemen: The Binoculars have given complete satisfaction. While confined at home by my accident, I had as perfect a view of the International Motor Boat trial races on Manhasset Bay as if I had been sitting on the Club House porch or following the races in a boat. The Binoculars form a part of my equipment. I would not be without them. Yours truly, JAMES E. SULLIVAN.

Offer a thousand uses for pleasure or utility.

[illegible]

This attachment serves not only to facilitate and accelerate in a remarkable degree the first stages of violin teaching, but to make up for past negligence in musical instruction, by training the pupil to a correct position of his fingers. About nine pupils *out of ten* may be said in this connection to be wanting in the accuracy conducive to correct playing. The figures 1, 2, 3, 4 correspond to the fingers of the left hand, aside from the thumb.

On the other hand, M. Choisy has endeavored to provide a similar help to beginners in piano playing. His "auxiliary keyboard" (*clavier simplificateur*), while not claiming to be anything like a substitute for the piano itself, can be used as a makeshift for practising and keeping up the dexterity of the fingers, without any instrument, the *arrangement of the* keys being the same as on the piano. The intention of the inventor, however, was mainly to remedy a defect only too frequent in the first stages of piano instruction, viz., confusion between the various octaves. In fact, even the most talented pupils are generally unable to recognize at a glance any notes situated above or below the five lines of the note system, the more so as sol-fa exercises, as generally practised, are after all, destined only for singing lessons. While this drawback could be helped by special sol-fa practice, adapted to the requirements of piano playing, this course would be rather complicated and trying to pupil and teacher alike.

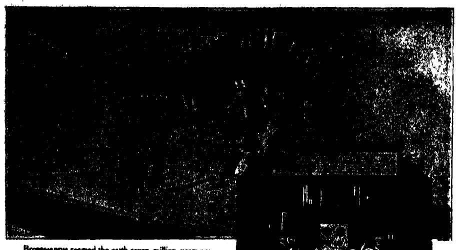
M. Choisy's auxiliary keyboard obtains the same result in a far more simple manner, and thus greatly facilitates piano teaching. It is simply applied behind, and immediately beside the piano keyboard, and will be found readily to remain in position. Inasmuch as all the notes of the instrument are inscribed on the auxiliary keyboard, the pupil, in the event of any uncertainty about a given note, will immediately find the key desired. The more he thus acquaints himself with the various octaves of the instruments, the more will he be able to do without the auxiliary keyboard, until its help can be entirely dispensed with.

Arctic Mines

APROPOS of the collieries in Spitzbergen, which have frequently been pointed out as an interesting example of mines in high latitudes, it may be worth noting that much coal from Spitzbergen is shipped to Kiruna, in Swedish Lapland, latitude 68⅓ degrees north (about the same latitude as northern Alaska), for use in operating the richest and probably the largest iron-mine in the world. According to a recent consular report, this mine is operated the year around, employs about 1,600 men, and is expected soon to be shipping 10,000,000 tons of ore per annum. About 25,000,000 tons have already been taken out. After this year the mine will be operated by electricity, the power being brought from Porjus Falls, 150 miles distant.

New Magnetic Charts of the Globe, or at least of regions of the earth embraced between 50 degrees north and 50 degrees south latitude, will, it is hoped, be published by the Department of Terrestrial Magnetism of the Carnegie Institution in 1915. They will include the three magnetic elements, declination, dip, and intensity of field, and will be referred to the date January 1st, 1910, as the middle date of all the material secured by the department and co-operating institutions during the period 1905-1915. It now seems likely that the polar regions can also be included, in view of the renewed activity in polar exploration. It has been the practice of the department to lend apparatus, train observers, and furnish instructions for all polar expeditions giving promise of serious and extensive magnetic work.

Sir Ernest Shackleton, accompanied by Messrs. Wild and Marston, members of the forthcoming antarctic expedition, will visit Norway at the end of March for the purpose of testing under polar conditions the sledges to be used by the expedition.



Brontosaurus roamed the earth seven million years ago. He could not adapt himself to changed conditions. Nature scrapped him.

One of the cases in the William J. Hammer Historical Collection in New York, which exhibits the hundreds of lamps which were scrapped before MAZDA Service gave us the MAZDA lamp of today.

Evolution and the Scrap Heap

Talks About MAZDA No. 4

"Not the name of a thing but the mark of a Service."

ABOUT seven million years ago, more or less, a stupid, slow-moving lizard known to science as *brontosaurus* roamed the earth. He stood thirty feet high on his hind feet and was seventy feet long. He weighed over thirty tons. As he lumbered along, each of his ponderous feet left a track that occupied one square yard. No one knows why he became extinct. Perhaps the earth shrugged her shoulders one day, as it were; in other words, a cataclysm occurred. Dry land became water and oceans became dry land. *Brontosaurus* could not adapt himself to the change. Nature scrapped him.

This process of scrapping is what Darwin meant by "evolution," "natural selection," and the "survival of the fittest." It is a process that finds its counterpart in the scrap heap of human industry. There are mechanical fossils as well as fossil lizards. Look in the scrap heap of any industry and you will find them. The bigger that scrap heap is, the more marked has been the evolution which it represents, the more perfect is the product of the industry. If an industry has no scrap heap it is standing still; it is not evolving.

Next to agriculture and architecture the oldest of human industries is the art of lighting. Hence the scrap heap of light producers ought to be large. And it is. Think of the hairy, low-browed savage who rubbed two sticks together, built a fire and thus made the first artificial light thousands and thousands of years ago. Then think of the incandescent electric lamp. What an evolution! What a scrap heap has been piled up of beacons, rush lights, candles and oil lamps, each with a little subsidiary scrap heap of its own, representing the evolution of its particular type of light-producer!

When the incandescent electric lamp was invented the height of the scrap heap was more than doubled. In a few years, lamps which represented the illuminating methods of centuries were discarded. And the end is not yet. The height of the scrap heap is growing more rapidly than ever.

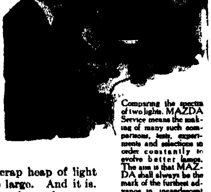
All the science of our time is epitomized in the incandescent lamp of today—the MAZDA lamp. If you knew its history you would know the history of modern science. Study its scrap heap and you learn how far the art of lighting has evolved, even in your own time.

At the very bottom of the heap you will find a lamp with a strip of graphite in a poor vacuum. Farther up are hundreds of lamps with platinum filaments, still further up lamps with filaments composed of the oxides of zirconium and titanium, and very near the present top, lamps with filaments of carbon, osmium, silicon compounds and tantalum. Then come many types of the metal filament lamp, including types of tungsten lamps.

All of them are as extinct as *Brontosaurus.*

Let it not be supposed that the lamps of today marked MAZDA are the last word in incandescent electric lighting. Some day there will be other lamps, more efficient but still marked MAZDA.

They will be so marked because they evolved from the same unceasing systematic study and selection that gave us the MAZDA of today—a study and selection centered in the Research Laboratories of the General Electric Company at Schenectady and supplemented by learning from the leading experimental lamp laboratories of the world, what progress they have made in the same direction.



Comparing the spectra of two lights. MAZDA Service means the making of many such comparisons, tests, experiments and selections in order constantly to evolve better lamps. The aim is that MAZDA shall always be the mark of the furthest advance in incandescent lighting

The results thus obtained are communicated to the General Electric Company's manufacturing centers at Cleveland and Harrison, and also to the other lamp manufacturing companies entitled to receive them. This scientific investigation and the communications of the results obtained constitute MAZDA service. All the lamps made by the companies in accordance with this service are marked MAZDA.

A lamp marked MAZDA is always the product of a scientific evolution; whether you buy it today, tomorrow, or at any future time, it is selected from types devised after months, and even years of research; it is the one that has survived all tests, because it has been proved the fittest; it is a lamp that represents the latest commercial advance in illumination of its time.

NEW BOOKS, ETC.

THE JOB, THE MAN, THE BOSS. By Dr. Katherine M. H. Blackford and Arthur Newcomb. Illustrated from photographs. Garden City and New York: Doubleday, Page & Co.

The man behind the machine is as important a factor as the man behind the gun on board a battleship; yet weeks and even months are spent in rearranging machinery with an eye to efficiency, and not ten minutes in selecting the man who will be charged with the care of that machinery. To bring system and order where hitherto there has been either chaos, or at the best reckless choosing, is the primary object of this book.

A plea is made for two principles: The establishment of a central employment bureau in every large organization and a character analysis of each employee, proposed or actually engaged, to determine his qualifications and fitness for a particular task

The idea of a central employment bureau is one that must commend itself at once. When it is considered that shop foremen select their own men, and in so doing are frequently governed by blind prejudice, that their "hire and fire" method is not only unfair to the employee but extremely costly to the employer, there can be no question that within the next few years we will see the central employment idea firmly established. The authors have introduced it with success in several factories. In accordance with their system, shop foremen send their requisitions to the central employment bureau for men just as they send requisitions to the pattern or tool department for patterns and tools. Human material which they cannot use is sent back to be otherwise employed if possible, and not to be recklessly discharged.

As a matter of fact, very little material is actually sent back That is due to the system of character analysis which Dr Blackford has devised, a system which seeks to introduce method where hitherto there has been only guessing or intuition Beyond question, a man's psychical attributes manifest themselves physically. Low brows, thick lips, shifting eyes, square jaws, have always symbolized well-known attributes, not only in novels but in the very practical affairs of daily life. Mental and other aptitudes Dr. Blackford has classified with their physical expression (skin texture, width of head, color, etc) in a way that anyone can grasp It is a matter of great importance, as practice has shown, whether a man who applies for a particular job is long headed or round headed, blonde or brunette, convex or concave in profile, high browed or low browed, fine skinned or coarse skinned. A scientific method takes the place of mere intuition and guessing

The system as it is outlined in this book has been in successful use in many large organizations, how successful may be gathered from the fact that it has been adopted by more than one plagiarist who has palmed it off as his own No doubt as it is more widely introduced, refinements and improvements will suggest themselves, but as it stands it is the first really scientific attempt to introduce definite principles, easily grasped, where there has been nothing but folly, ignorance and injustice.

THOMAS'S REGISTER OF AMERICAN MANUFACTURERS. And First Hands in All Lines. New York: Thomas Publishing Company, 1914. Sixth edition. 2,800 pp. Price, $15.

The Register has developed into a ponderous tome very much larger than Webster's Unabridged, and presents improvements both in content and arrangement A new section has been added, containing 50,000 names in straight alphabetical order. From the name of a concern, one may thus locate its offices, branches, and line of manufacture. This list, like the main classification of the volume, carries symbols indicating the capitalization and size of the listed firm. There is no line of business that is not adequately covered by the Register. That there are more than 70,000 completely-indexed classifications is sufficient evidence that all available names, regardless of advertising patronage, are included. There is also an alphabetical list of trade names and special brands, showing the manufacturers of each. The Register affords the buyer immediate access to every possible source of supply, while to the seller it offers a compilation of possible customers with intimate information of their standing, in so far as this is indicated by money invested.

THE WORLD SET FREE. By H. G. Wells. New York: E. P. Dutton & Co., 1914.

This latest of Mr. Wells' books is a curious combination of his earliest and latest methods, for it is at once one of those magnificent flights of imagination which gave us the "Time Machine" and the "War of the Worlds," and the keen sociological perception which gave us the "New Machiavelli" and its successors. How the great world war started, how it was fought with the aid of aeroplanes and atomic bombs, how it became so terrible that the utter folly of fighting was driven home with telling horror, Mr. Wells sets forth with a vividness that stamps him as a literary artist of the first rank. To the scientist, of course, the most interesting feature of the book is the method in which the discoveries in radio-activity are given artistic treatment, a method which shows that in the hands of a master science offers possibilities that can hardly be overrated. The atomic bomb which plays so great a part in this story, although a creation of Mr. Wells, may be regarded as inspired by Soddy's "Interpretation of Radium." Wells argues that inasmuch as radio-active substances are constantly decaying and giving off energy as they do so, tremendous results could be obtained if the decay could occur with explosive rapidity. Trained scientist as he is, he presents his atomic bomb with an air of definiteness and conclusive-

"My oil seems to work all right"

This hap-hazard expression is common among inexperienced motorists. It often brings costly penalties.

The motorist should never rest satisfied simply because he *sees* no trouble.

You cannot spare time to frequently examine your wrist-pins and bearings. Nor can you, after each run, inspect your cylinder walls and piston rings for signs of faulty lubrication.

Every good automobile motor is built to stand abuse —for a time.

No matter how inefficient your oil is, your motor for a while will "seem to work all right."

But high fuel bills often point to power-waste—sometimes directly due to incorrect oil.

And the poorly-lubricated motor which "seemed to work all right" too-commonly is headed for the repair shop.

Lubricating oil, to prevent power-waste and premature motor wear, *must* have two qualities.

(1) Its *body* must be suited to your feed system, piston-clearance, bearing design and many other important factors which differ with different motors.

(2) Its *quality* must give full protection to the moving parts under the heat of service.

How can you make sure that your lubricant is correct in body and high in quality?

A safe, scientific guide will be found in the carefully-studied recommendations listed in the Lubricating Chart printed in part at the right. Each recommendation in this chart was made after a careful engineering analysis of the car's motor.

For a number of years this Chart has been the standard scientific guide to correct lubrication.

A copy of our complete Chart will be sent you on request

On request we will also mail a pamphlet on the Construction, Operation and Lubrication of Automobile Engines It describes in detail common engine troubles and gives their causes and remedies.

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are

Gargoyle Mobiloil "A,"
Gargoyle Mobiloil "B,"
Gargoyle Mobiloil "E,"
Gargoyle Mobiloil "Arctic."

They can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants

It is safest to buy in original barrels, half-barrels and sealed five and one-gallon cans. See that the red Gargoyle, our mark of manufacture, is on the container

For information, kindly address any inquiry to our nearest office The city address will be sufficient

Correct Lubrication

Explanation In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used For example "A" means "Gargoyle Mobiloil A" "Arc" means "Gargoyle Mobiloil Arctic" For all electric vehicles use Gargoyle Mobiloil "A" The recommendations cover all models of both pleasure and commercial vehicles unless otherwise noted

Soldering and Brazing

for nearly all metals, including such difficult ones as cast iron and aluminium, have been the subjects of hundreds of paragraphs in the Scientific American Supplement. We quote a few of the more important articles, as follows:

Scientific American Supplement No. 1673—*Full Instructions for Mending or Welding Cast Iron,* gives both brazing solders and fluxes necessary.

Scientific American Supplement No. 1713—*Brazing Cast Iron and Other Metals,* gives detailed instructions for the whole operation, and formulas.

Scientific American Supplement No. 1644—*Soldering and Soldering Processes,* gives broad general information, and contains in particular a method for pulverizing solders and alloys of great use.

Scientific American Supplement No 1667—*Some Soldering Appliances,* describes the blow-pipe and the furnace in their various forms.

Scientific American Supplement No. 1481—*Soldering of Metals and Preparation of Solders* gives many formulas for soft and hard solders and fluxes.

Scientific American Supplement Nos. 1610, 1622, 1628 contain a series of three articles on Solders, covering the entire range of solders for all metals No. 1628 contains formulas for *soldering aluminium.*

FOR 80 cents - the price of the eight numbers, postpaid, the purchaser of these Supplements has a complete treatise on the subject of Soldering and Brazing, containing formulas of the greatest value.

EACH number of the Scientific American or the Supplement costs 10 cents A set of papers containing all the articles here mentioned will be mailed for 80 cents. Send for a copy of the 1910 Supplement Catalogue, free to any address. Order from your newsdealer or the publishers

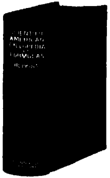
The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Eighth Edition of
"The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by **ALBERT A. HOPKINS,** Query Editor of the Scientific American



THIS is practically a ***new book*** and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters:

I. Accidents and Emergencies.
II. Agriculture.
III. Alloys and Amalgams.
IV. Art and Artists' Materials.
V. Beverages; Non-Alcoholic and Alcoholic.
VI. Cleansing, Bleaching, Renovating and Protecting.
VII. Cements, Glues, Pastes and Mucilages.
VIII. Coloring of Metals, Bronzing, etc.
IX. Dyeing.
X. Electrometallurgy and Coating of Metals.
XI. Glass.
XII. Heat Treatment of Metals.
XIII. Household Formulas.
XIV. Ice Cream and Confectionery.
XV. Insecticides, Extermination of Vermin
XVI. Lapidary Art, Bone, Ivory, etc.
XVII. Leather.
XVIII. Lubricants.
XIX. Paints, Varnishes, etc.
XX. Photography.
XXI. Preserving, Canning, Pickling, etc.
XXII. Rubber, Gutta-Percha and Celluloid
XXIII. Soaps and Candles.
XXIV. Soldering.
XXV. Toilet Preparations, including Perfumery.
XXVI. Waterproofing and Fireproofing.
XXVII. Writing Material,
Appendix: Miscellaneous Formulas; Chemical Manipulation; Weights and Measures; Index.

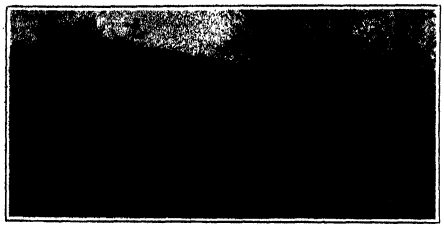
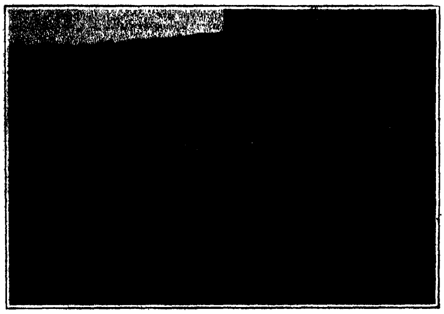
Grading into different height classes.

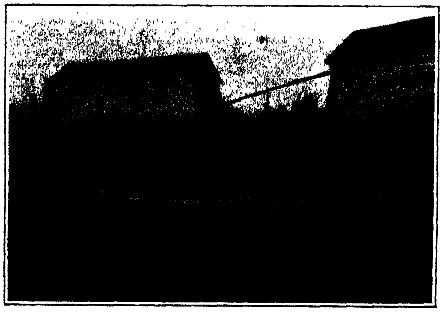


Drying and bleaching peeled willows.

Peeling the willow rods.



Tying the peeled rods into bundles for storage or shipment.



Bundles of American green willows in the pit ready to be peeled.

Basket Willow Culture in the United States

BASKET willows are of European origin and are now cultivated in all temperate climates. They thrive as far north as Norway and Sweden, and have been naturalized in portions of North and South America, Australia, and New Zealand. They are grown extensively in Great Britain, France, Belgium, Holland, Germany, Austria, and Russia. The chief producing districts of Europe are Germany, Holland, and France, where the conditions are particularly adapted to willows. These are highly esteemed by American basket makers, who use several thousand tons of imported rods annually. Willows grown in Belgium are also among the finest, but they are usually larger and suited principally for coarser basket ware.

There are many kinds of basket willows in cultivation, and much confusion exists in their classification. About ninety-five different strains considered valuable commercially are known in Europe. The varieties now most in use in this country are purple willow (*Salix purpurea*), American green willow (*Salix amygdalina*), Lemley willow (*Salix pruinosa*), and Patent Lemley willow (*Salix pruinosa acutifolia*). The purple willow is by far the best variety for American conditions, and it has been grown successfully from Maine to Minnesota and southward to Kentucky and Tennessee. It readily adapts itself to a great variety of climatic and soil conditions and produces tough, pliable rods much sought by basket makers. Climate and soil have much to do with the successful cultivation of willows. In regions with a mild and humid atmosphere the best length of rods and, therefore, the greatest yield per acre is obtained. Loose, rich, and moist sandy loam soil is most congenial to their growth. Willows may be grown in any part of the United States where these soil conditions obtain, and when rationally treated no other crop gives more profit. The difference in quality of willow rods does not arise so much from the difference in kind as it does from the result of soil and general treatment. The same variety will produce good, long flexible rods in one part of the plantation, while in another they may be short, brittle, and branching.

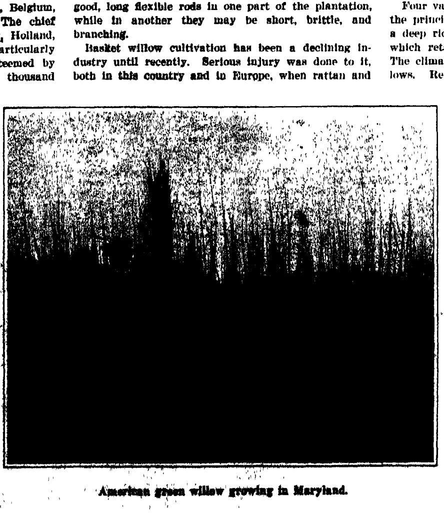
Basket willow cultivation has been a declining industry until recently. Serious injury was done to it, both in this country and in Europe, when rattan and other substitutes began to be introduced. The prevailing low prices of splint baskets and sea-grass furniture are also factors in its decline. The demand for willows is again increasing, and a brief discussion of their culture followed in the willow-growing districts should, therefore, be of interest.

Four varieties are grown in northern New York, but the principal kind is the purple. The soil chosen is a deep rich humus with a moderate amount of sand, which retains the required amount of soil moisture. The climatic conditions are likewise favorable to willows. Reports covering ten years show an average annual rainfall of 35 inches. This amount of moisture is an essential condition for the attainment of a good crop The willow zone of northern New York is thus largely determined by the peculiar character of the soil

The ground is prepared so as to clean it of weeds, and place it in a condition to facilitate the wide penetration of the roots of the willow, and also to conserve moisture during hot weather. The success of this work, like in all other undertakings, depends upon the management, which must be in the hands of men who are able personally to direct the work and who have at the same time a material interest in the welfare of the plantation In New York most willow plantations are owned by farmers who cultivate and harvest their own crops. No systematic method of manuring has as yet been undertaken. A few growers use well-rotted barnyard manure and spread it between the rows and work it in the upper stratum.

Cuttings are planted early in March, and the operation is intrusted only to those who have knowledge of the work. The length of the cuttings should vary

(Concluded on page 453.)



American green willow growing in Maryland.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Latin-American Attitude to the United States

FOR the reason that we believe it represents the attitude of the intelligent Latin-Americans toward the foreign policy of the United States, at least so far as it affects the Western Hemisphere, we publish with much pleasure, and direct special attention to the letter from a correspondent in Cuba, which will be found on our correspondence page. The writer has appreciated at their full value the motives and convictions which prompted our publication of the series of articles entitled "The Problem of Our Navy;" and we believe that if toll could be taken of the opinion of the more intelligent citizens of the Latin-American countries, it would be found that there is a general appreciation of the fact that the best guarantee of the inviolability of the New World against armed aggression by the nations of the Old World, is the possession by the United States of a fleet of such power, and in a condition of such thorough preparedness, that none of the navies of the Old World could measure arms with it, in the waters of the Western Hemisphere, without running the risk of a defeat

It is discouraging, in view of what we have done in Cuba, to realize that there is a certain amount of distrust of the United States existing among the great mass of the people of the Latin-American republics As an instance of disinterested and highly idealistic attitude toward a weaker state, the United States may point to the history of our relations with Cuba with a pride which is altogether justifiable. We entered that distracted island for the express purpose of regulating its many disorders and with the definite statement that we had no wish to permanently occupy territory, and with a pledge, further, to withdraw our forces as soon as a stable government had been established. That pledge we have fulfilled to the letter; and Cuba stands to-day as an undeniable proof of the fact, first, that the attitude of the Government of this country to the rest of Latin-America is altruistic, in so far as we earnestly desire to see it prosper under strong, independent, and capable governments; second, that our attitude is egotistic only so far as our Government realizes that the abolition of revolutions, the harmonizing of contending factions and the setting up of orderly governments, conduces to the prosperity of the United States and promotes the advancement and solidarity of the Western Hemisphere as a whole.

Air and Water Resistance of the Racing Yacht

THE resistances which have to be overcome in getting speed out of a racing yacht, especially if she is going to windward, may be broadly divided into those which are encountered respectively above and below the water-line. Although by far the greater part of the sail power is expended in driving the hull through the water, not a little of it (much more than would be generally supposed) is absorbed in forcing the towering superstructure of sail, mast, and wire rigging against the wind.

Although it may seem paradoxical to say that the wind power which drives the yacht forward tends also to hold her back, it is a fact that when a yacht is close-hauled or heading into the wind, the head resistance of the wind and its skin-friction along the sails, total up a very considerable amount When a yacht is making 10 knots against a 25-knot wind, the resultant wind velocity through her rigging will be about 30 knots. This is well understood by the yacht designer; and, during the races of the past fifteen years, great attention has been paid to this element of the problem. It so happens that the constant endeavor to save weight aloft, by the substitution of hollow steel masts and steel wire for wooden masts and manila rope, has also tended to reduce dimensions, and so cut down head-wind resistance. When we bear in mind that the standing and running gear of a modern racing yacht will total up from 2,500 to 3,000, or even 3,500 linear feet, and that the mast of an "America" cup yacht will present a total square surface of nearly 200 square feet to the wind, it will be understood that, in races that are sometimes won by seconds, the question of wind resistance is an important one. In addition to head resistance there is the skin-friction of the wind along the sails, and it is somewhat in the effort to lessen this that in a modern yacht the cloths of the sails are run approximately horizontally, so that the flow of the wind may be more along the seams than across them.

The resistance of the hull may be classified under wave-making; eddy-making; suction or drag; and skin resistance. Wave-making is the most important element of resistance at the higher speeds, and increases very rapidly with the increase of speed; in light airs and at the lower speeds skin resistance, or the friction of the water against the wetted surface of the hull, is the more important. Wave-making is due to the rapid displacement of the water as the yacht progresses, and its magnitude for a given speed is, of course, greatly affected by the underwater model of the yacht. At the higher speeds a mass of water is continually being lifted in the form of waves to a certain height above the general water level. This means that work is being done upon the water, and that a proportional amount of the driving energy of the wind is being thus absorbed. If there is anything wrong with the model of the yacht, especially in her run and quarters, and the stern wave does not rise snugly along the quarters, but follows several feet astern of the yacht, there will be heavy drag, and she will tend to pull a certain amount of water after her, and this will mean a further consumption of energy.

The designing of a yacht, such as those which contend for the "America's" cup, is complicated by the fact that the weather conditions throughout a season's yachting will vary from gentle airs to very strong winds; and the most successful yacht, other things being equal, will be the one that maintains the best mean speed under the average of all weather conditions.

Past experience, extending over more than a quarter of a century, has proved that on the race course off Sandy Hook the prevailing winds are light; and hence, of two well-designed and equally well-sailed yachts, the one which presents the largest amount of sail area per square foot of wetted surface should prove to be the winner of a series of races—this for the reason that, at moderate speeds, the skin friction is the most important element of resistance. Our American yacht designers seem to have recognized this fact, or, at least, they have paid more attention to it than the British challengers; for it is a fact that, with sheets started, in light airs, our yachts have always won out by a handsome margin. In the one case in which the challenger has pulled away from the home boat when running before the wind ("Shamrock II" versus "Columbia"), the "Shamrock" spread about 1,000 square feet more of canvas than "Columbia" above a hull which probably had somewhat less wetted surface.

There is one other element of resistance, the importance of which can scarcely be over-estimated, and that is the drag due to the rudder. Theoretically, in a properly designed yacht, in which the center of wind pressure is in the correct position with regard to the center of the vertical underwater plane of the hull, the rudder, even when the yacht is sailing close-hauled, should be practically amidships. The least putting over of the helm produces a corresponding drag upon the hull, with a resulting loss of speed. A well-balanced yacht should carry a slight weather helm in going to windward; but an experienced captain will pay such close attention to the trim of his sails that he will practically eliminate this; and it is our belief that the remarkable results obtained by the late Capt. Barr in working to windward in light airs, was largely due to his appreciation of this fact.

The Protection of Our Migratory Birds

OUR farmers suffer a loss of $800,000,000 annually from the ravages of the boll-weevil, the gypsy moth, the Colorado beetle, the rush fly, the codling moth, the white scale, and many other pernicious insects. Congress has from time to time authorized the expenditure of millions for the extermination of these pests, and yet Congress hesitates adequately to protect birds which are known to be the natural enemies of destructive insects.

Most insects like the green leaf louse, or aphis, so ruinous to the hop industry, and many other of our most valuable fruits and vegetables, reproduce their kind at the rate of ten sextillion to the pair in one season. The natural increase of one pair of gypsy moths would defoliage the United States in eight years. Locusts, army worms, and chinch bugs, unless checked in procreation, soon become countless hordes, devastating wide areas of the earth's surface. Dr. Lintner of the New Jersey Board of Agriculture reports that one hundred and seventy-six species of insects attack the apple tree. Approximately the same number attack peach, plum, and cherry trees. Dr. Packard finds four hundred species feeding upon the oak; and three hundred attacking the conifers. The number feeding upon cereals, grains, and garden crops is huge. Dr. Marlatt estimates that the loss to the wheat-growing States in 1904, occasioned by the Hessian fly, was about $50,000,000, and Dr. Shinar places the damage done to crops in the Mississippi Valley by the chinch bug in one year as high as $100,000,000. The Rocky Mountain locust, during the years of its greatest activity, caused a loss to the States of the Northwest of more than $150,000,000. Cut worms, Dr. Lintner assures us, mean an annual loss to farmers of $100,000,000. Clearly, it is not a gross exaggeration to place the damage to our crops and fruit trees at $800,000,000 annually.

Under most State laws, local game is adequately protected; for the average open season does not exceed six weeks, and often no shooting or fishing is allowed for several years. With migratory birds the open season often exceeds eight or nine months. This means eventual extermination under State regulations, and with the destruction of wild fowl and insectivorous birds the entire nation suffers. Each woodpecker is worth $20 to this country, according to the Department of Agriculture.

Certain varieties of snipe are now extinct, and the remainder, but a straggling remnant, is still being shot ten months in the year. In 1857, an Ohio's Senate Committee's report stated: "The passenger pigeon needs no protection." Fifty-five years after this was written the bird which existed in countless millions became totally extinct.

At one season of the year practically all the ducks of the United States are crowded in the marshes and swamps of Louisiana and Florida; for there food is abundant. Hence, it is difficult to convince the people of the South that there is any scarcity of wild water fowl. The official record of wild fowl killed in Louisiana during the season of 1910 is as follows: Wild ducks, sea and river, 3,176,000; coots, 280,740; geese and brant, 202,210; snipe and plover, 696,635. At this rate our migratory birds will be extinct in a few decades.

The early idea predominated that any restriction imposed upon the right to make assaults upon nature's storehouse was a restriction and an abridgment of human liberty and, therefore, hostile to the principles of free government. More recently the American people have become thoroughly awakened to the imperative necessity of conserving our natural resources, and among those resources wild birds are not the least important.

The Weeks-Maclean law is intended to protect our migratory birds, but Congress has manifested no great desire to make it effective by appropriating a suitable sum for its enforcement. The sum of $100,000 which was asked will not provide even a single Federal warden for every State. It takes about $2,500 to cover the annual pay and traveling expenses of such an official. On the other hand, to prevent the adulteration of Paris green and other insecticides Congress appropriates $95,000; to establish an agricultural experiment station on the island of Guam, $15,000; to fight gypsy and brown-tail moths, $297,540; to fight cotton boll-weevil and for farmers' co-operative demonstrations, $628,240; improvement of tobacco, $28,000; investigation of plant diseases, including diseases of ginseng, etc., $37,000. The protection of migratory birds is no less important than the erection of a station at Guam, or the prevention of adulteration of insecticides.

The Canadian government has prohibited the shooting of wild fowl in all its great Provinces, and it expects this Government to do likewise. Neither country is concerned about the State or provincial laws, regulating the shooting of local birds in the home district of their neighbor, but much interested in proper laws for the preservation of game in which each has an interest and a duty. Fully 75 per cent of the migratory game birds are raised in Canada; yet American game butchers, immediately beyond the Canadian border line and along the passage of migratory flight, claim the legal right of exterminating birds as they see fit.

Thanks to the activities of the American Game Protective Association, there is every prospect that a treaty will be enacted between the United States and Great Britain which will stop the reckless slaughter of migratory birds that has gone unchecked for generations on the North American continent. When that treaty is ratified migratory birds will be protected during nearly the complete line of their flight.

Engineering

Launching of Cup-Defender "Defiance."—"Defiance," designed by Owen, built at the Bath Iron Works, and launched at the yards of this company, is now under sail. The yacht has been built by what is known as the tri-city syndicate, of which Mr. George S. Pynchon is chairman. She is of composite construction, with steel frames covered by two thicknesses of wood, one of fir, the other of mahogany. A full description of the yacht appeared in our issues of May 2nd and May 9th.

The Destroyer "MacDougal" Makes 32.07 Knots.—While running her standardization trials the new destroyer "MacDougal," built at the Bath Iron Works, made a maximum speed of 32.07 knots for one mile and averaged for five full-speed runs 31.52 knots. The "MacDougal", measures 300 feet on the water-line, 30½ feet beam, 9 feet 5 inches draft, and displacement is 1,025 tons. She is armed with four 4-inch 50-caliber guns and eight 18-inch torpedo tubes. She is an oil burner, carrying a supply of 309 tons of oil.

Behavior of Concrete in Sea Water.—In 1909 several reinforced concrete posts made from different materials of different proportions and in varying degrees of thickness, were submerged in sea water at Boston, where they have been exposed to tide variations and ice conditions. A recent booklet of the Aberthaw Construction Company of that city states that thus far it has been determined that a dense concrete will better resist the combined physical and chemical action of sea water, flotsam and ice than will a porous concrete.

Alaskan Engineering Commission.—President Wilson has appointed the members of the commission which is to have charge of the location and construction of Government railways to be built in Alaska. The commission consists of Messrs. Edes, Mears and Riggs, who are now on their way to Seward, Alaska, which will form the headquarters for the Summer. The first work to be done will be the survey of a route from Portage Bay to the vicinity of Fairbanks. Applicants for work on the engineering force should address the Alaskan Engineering Commission, Department of the Interior, Washington, D. C.

An Ancient Horse-drawn Train Service.—According to the *Engineer*, it was only last month that there was brought to a close a passenger train service maintained by horse traction, which has been in continual operation since the year 1856. The stretch of line affected is a portion of the North British Railway, lying between Drumburgh Junction, a few miles west of Carlisle, and Port Carlisle, a seaport on the Solway Firth. The line was operated by locomotives from 1854 to 1856, and in August of the latter year horses were substituted. They have been in continuous use up to the present year, when they were superseded by steam locomotives.

A 113-mile Electrification of a Steam Railroad.—The Chicago, Milwaukee & St. Paul Railroad is about to electrify a portion of a 440-mile stretch of railroad across the Belt, Rocky and Route Mountain ranges. The first section will be 113 miles in length. Direct-current, 2,400-volt traction will be adopted, and regenerative electric braking will be used instead of the customary air braking. The section will be operated with twelve 200-ton freight locomotives, four 200-ton through passenger locomotives and two 100-ton local passenger locomotives. The estimated cost of the installation is $1,500,000, exclusive, of course, of the cost of the locomotives.

The Stress of Sea Waves.—In his recent lecture before the Royal Institution at London, on modern ships, Sir John Lyle drew attention to the fact that, when the waves are one half the length of the ship and one twentieth of the length in height, the stress upon the ship itself was very little increased above that in smooth water. But when the waves are of the same length as the ship, or one and one half times its length, the stresses are considerably higher than when the ship is in smooth water. Hence, in view of the fact that waves are seldom over 500 feet long, the maximum bending moments which come upon a ship 900 feet long, such as the "Aquitania," are much less than those which come upon one 500 feet in length.

Canal-Boat Elevator.—A somewhat original construction in the shape of a canal-boat elevator is in use on one of the canals in the north of France which connects the ports of Dunkerque and Calais with the industrial and mining region. It consists of two metallic basins lying side by side and about 130 feet in length. Each tank is carried on a vertical hydraulic piston, one tank rising while the second one falls. Connection with the ends of the canal is made by a system of gates and also a rubber tube joint between tank and canal end, the rubber tube being filled out by compressed air so as to make a tight joint, whereupon the gates are opened. One tank being at the top and the second at the bottom, the joint is made at the top tank, the gates withdrawn, and water enters the top tank to the level of 8 feet. After the canal-boat is run into the tank the gates are closed.

Science

The Preparation of Eye-Preserving Glass for Spectacles.—Sir William Crookes recently read a paper before the Royal Society of London, in which he points out how the injurious ultra-violet rays of the sun may be cut off so as to protect the eyes in tropical countries. Experiments made by Sir William to protect the eyes of blowers of glass vessels resulted in the discovery of a composition of glass, sage green in color, that cuts off 98 per cent of the heat rays. This glass is composed of ferrous oxalate, soda flux, red tartar and powdered wood charcoal. Sir William's experiments showed that it was possible to make no less than six different glasses to shield the eyes from heat rays. Sir William gives complete details, and explains how the glasses are made in his paper.

The Roosevelt South American Trophies.—Most of the 2,500 specimens of big game, mammals and birds bagged by George K. Cherrie and Leo E. Miller, members of the Roosevelt-Rondon expedition, have arrived at the American Museum of Natural History. Many of the specimens in the collection are new to the museum, and possibly some are new to science. Mr. Miller, mammalogist of the party, covered some 3,000 miles in exploration and collecting trophies for the museum. He first went up the Paraguay in steamers and launches as far as the river was navigable, and then he proceeded on a 500-mile jaunt over land, traveling on muleback. For forty days he journeyed through a country with little vegetation and through a desert-like region.

Piano Touch.—It is usually considered that no mechanical piano player, however excellently constructed, can reproduce the exact efforts produced by human touch. From the analysis of Prof. Bryan, it would appear that this belief must yield to scientific analysis. He analyses the precise meaning to be attached to "touch," and shows that it may be perfectly reproduced on a pneumatic piano by means of an auxiliary lever which operates directly on the bellows, and is regulated by a sliding weight gliding on the lever itself, or by the direct pressure of the hand. The analysis is very thorough and scientific, and it is perhaps a mere confession of human weakness to say that it does not entirely convince one who has heard Pachmann play Chopin.

The Brazilian Expedition of the University of Pennsylvania, under Dr. W. C. Farabee, has completed a year of arduous and remarkably fruitful explorations, the first of which were made along some of the northern tributaries of the Amazon beyond the limits of previous exploration, while the more recent work has been done in the highlands lying on the frontier between Brazil and the Guianas. Last November Dr. Farabee started from Dadanawa with 40 native carriers on an easterly march through completely unknown territory, in the course of which he discovered several new tribes, none of which had ever before seen white men, guns, clothing or matches. The natives of this region are among the most primitive savages in the world. The explorers reached Georgetown, British Guiana, April 19th.

The Sedov Relief Expedition which the Russian government is sending north this Summer now gives promise of being a more elaborate undertaking than was originally contemplated, and, whether it succeeds or not in finding Capt. Sedov and his companions, will probably achieve interesting geographical results. It will consist of the steamers "Hertha" and "Andromeda" and the motor-vessel "Tatiana." These boats will first visit the Pancratiev Islands, off the coast of Nova Zembla, the last known location of Sedov's party, and the place from which he expected to start last Summer for Franz Josef Land. If he is not still there, the "Hertha" will take the stores from the "Tatiana," together with dogs and sledges, and endeavor to reach Franz Josef Land, while the "Andromeda" will cruise north along the coast of Nova Zembla, and the "Tatiana" will return to Archangel. The "Hertha" may find it necessary to Winter in Franz Josef Land. Her equipment includes a hydroaeroplane.

The Stackhouse Antarctic Expedition will not be able to leave England in August, as was originally intended, and may be postponed until next year. The earlier announcements regarding this expedition indicated that its principal object was to be the exploration of King Edward VII. Land, but the plans appear to have been gradually modified with the progress of time. The latest announcement is that the expedition will first land a party of twelve men on Graham Land to carry on scientific work there, while the ship will proceed along the coast, and probably winter somewhere near Prince Regent Luitpold Land, where the Austrian expedition under König, and the British expedition under Shackleton, also expect to have their Winter quarters. In the Antarctic Spring of 1915, it is proposed to have the ship pick up the Graham Land party, and, after coaling at Deception Island, to survey the west coast of Graham Land, and pass the next Winter in the neighborhood of Charcot Land. The following season, an attempt will be made to trace the supposed coast-line all the way west to King Edward VII. Land.

Automobile

An Improved Carbureter.—Patent No. 1,092,953 to Augustus M. Sanborn of Stanford University, Cal., is for a carbureter in which the hydrocarbon is mechanically projected into the air current in the form of a circumferential spray.

Puncturing Tires to Stop Automobiles.—Automobiles do not always stop when ordered by constables or other law officers, and Constant Le Duc of Chatsworth, N. J., in patent No. 1,094,226 provides an implement which can be extended so as to bring it into the path of a vehicle. The spurs on the implement will puncture the pneumatic tires, thus bringing the vehicle to a stop.

Motor 'Bus Service in Saxony.—The Saxony government has appropriated the sum of $450,000 for the purpose of extending the working length of its State motor omnibus lines from 200 to 700 kilometers. Nineteen new lines will be established and two private lines taken over; an existing State passenger line also is to be taken over and extended for the transportation of merchandise.

Another American Knight Patent Issued.—After having been in the mills of the United States Patent Office for eight years—the application was made in 1906—patent No. 1,090,991 has but recently been issued to Charles Y. Knight, the inventor of the sleeve valve engine that bears his name. The patent supplements another issued in 1910 and covering a single sleeve valve engine. The new patent, which has 43 claims, covers the well-known Knight sleeve valve mechanism and also deals with an improved lubrication system.

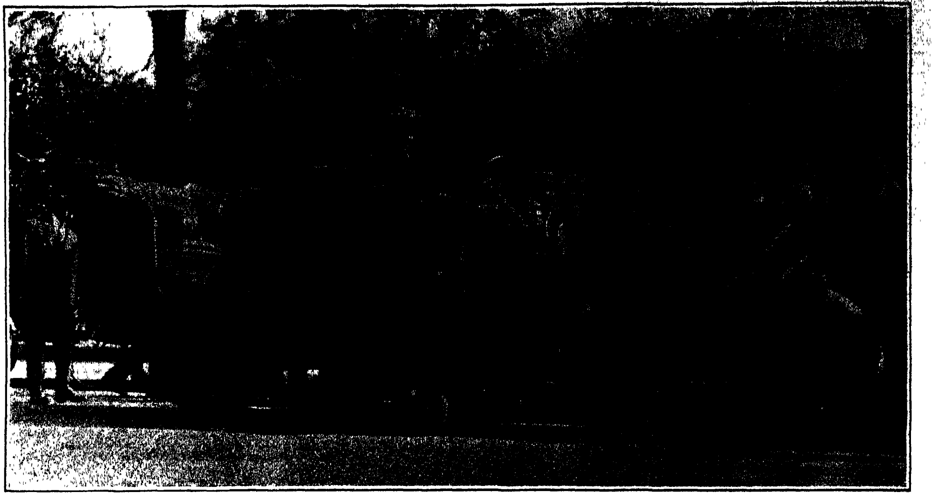
Fenders Leave Something to be Desired.—After having had ample time in which to test out the efficiency of the fenders required by law on commercial vehicles in the city of Detroit, owners of vehicles and drivers are practically unanimous that they are not of much use in preventing accidents—for which they were intended—and that they hamper the movements of the vehicles. It is pointed out in particular that the use of fenders considerably increases the over-all length of the vehicle and so shortens its turning radius; furthermore, fenders are easily damaged.

Use of Compressed Air in Steel Hardening.—Recently there has been adopted in a foreign motor car factory a new method of hardening steel with jets of compressed air. The usual method of hardening steel by immersion in oil or water or alkaline baths, it is said, results in the formation of a line of considerable tension between the hardened and unhardened parts. By the use of compressed air, however, the zones of cooling may be carefully graduated and much better results obtained. By adapting the shape of the nozzle to the work, a wide range of results is possible.

Horses are Really Going.—The statement "the horse must go" has been reiterated so often that it no longer attracts attention. But the horse really is going—and going fast. Of thirty-one principal American cities, sixteen show a noteworthy decrease in the number of licensed horse-drawn vehicles in relation to population. The percentages of decrease in seven of these cities, as collected by an organization of horse interests, are suggestive. They are as follows: Indianapolis, 11.5; Columbus, Ohio, 5.9; San Francisco, 4.8; St. Louis, 2.4, Omaha, 2.1; New York, 0.8; Chicago, 0.5. In the other nine cities the average decrease has been 2 per cent, whereas the average increase in population has been 7.8 per cent per year.

Foot-operated Gear Shifter.—The electric gear shifter now has become fairly common and there are several devices of the kind operated by compressed air. Now, however, there has appeared another which is operated by the movement of the clutch pedal. It has just been placed upon the market. The apparatus consists of a selector which is placed adjacent to the steering wheel, the shifting mechanism itself weighing about 10 pounds and attaching directly to the gear box. In operation, the driver selects the gear he desires, and the subsequent depression of the clutch pedal shifts the gears automatically. If a gear selected is not wanted, and it is deemed expedient to use another, the selection of the other disengages the first.

Novel Type of Cyclecar Drive.—There has been placed upon the market lately a cyclecar which has an unusually novel method of power transmission. The vehicle is propelled through one front wheel and not, as ordinarily is the case, through two rear wheels. To obtain the necessary changes in gear ratio there is a friction transmission mechanism in which the driving plate is the front of the flywheel, which, in this case, is ahead of instead of behind the engine. The driven member of the transmission is slidably mounted, so that it can be shifted across the face of the driving disk, and is connected to the front wheel drive through the intermediary of a universal joint and internal spur gearing within the wheel hub. It is claimed that ample traction is obtained and that skidding is avoided for the reason that the propelling power is a pull rather than a push.



The Schilowsky monotrack automobile.

The Principle of the Bicycle Applied to the Motor Car

A Two-wheeled Automobile Stabilized by Means of a Gyroscope

THE gyroscope and its applications need no introduction to our readers Its use for stabilizing ships, for steadying torpedoes and for ships' compasses, are all well known. Efforts have also been made to adapt the gyroscope for the automatic stabilizing of aeroplanes. Its use by Brennan to maintain the equilibrium of a monorail car is fresh in our memories. The latest development is a two-wheeled automobile, designed by the Russian engineer, P Schilowski, which is kept balanced by a gyroscope mounted on the machine. The car is shown in the accompanying halftone illustration It is a full-size vehicle, capable of carrying from four to six people on an ordinary road track

Its inventor, in a paper recently presented before the Royal Institute of London, summed up in the following words some of his conclusions relating to the principles to be observed in the design of such cars

The most desirable method of suspension of a gyroscope for stabilizing a monorail or a monotrack car is suspension below the center of gravity of the wheel, or neutral suspension with a top load, as it permits of the vehicle taking smooth curves in each direction Increasing the instability of the gyroscope, by adding to the top load, allows the vehicle to take sharper curves.

A special device for hurrying up the precession is unavoidable in any gyroscopic vehicle which must take sharp curves in the same direction as the rotation of the flywheel

However the gyroscope may be mounted, and in whatever direction the vehicle must run, in order to maintain the equilibrium of unstable bodies for any length of time, it is absolutely necessary to apply a *precessional system for restoring the plane of the wheel* whenever precession takes place, and it is not sufficient to increase the stability of the gyroscope by only increasing the speed. The only instance in which a device for hurrying up the precession is not required to bring back the gyroscope to its normal position, after it has been disturbed, is that of the common peg top spinning on a rough surface. In this case, the gyroscope must be entirely free of any support or mechanism, and the friction between the rounded axle and the surface on which the top is spinning automatically hurries up the precession and the top rises again.

The car, when running at a high speed, can with safety only take a curve increasing gradually in steepness Beyond a certain point dangerous oscillatory disturbances would be produced. Here we come into conflict with statements which are often found in technical books, that gyroscopic vehicles can, by their very nature, take the sharpest of curves. As a matter of fact, if a sharp bend has to be made, the curve must be gradually increased somewhat after the manner of a parabola or ellipse.

The details of the gyroscope mechanism are illustrated in the accompanying diagrams. For these and the data relating to them we are indebted to *The Engineer* They relate strictly to a monorail car, built by Mr. Schilowsky, but the principle is exactly the same as that employed in the bicycle-automobile.

Starting with Fig. 1, we have here a cross-section of the car, *A* being the central girder and *B B* the side frames. On the girder *A* and directly over the center line of the car wheels *C* a pillar *D* is erected At its top this pillar carries rigidly two parallel arms *E E* Two pendulums *F F* are hung from these arms, the bobs *G* of which consist of cylinders having their axes parallel with the longitudinal axis of the car. To the cross arms *E* two cords *H* are attached. These cords, passing vertically downward, are accommodated in shallow grooves running round the circumference of the bobs, and are thereafter taken round pulleys *J* journaled on the frames *B*. From these pulleys the cords pass vertically upward. When the car is on an "even keel" the cords are required just to touch the bottom of the grooves on the bobs. For facilitating adjustment in this respect the ends of the cords are attached to lever arms *K* formed on spindles pivoted between the members *E*. Opposed arms on these spindles are acted upon by the ends of small screw handles *L*.

Coming now to Fig. 2, an elevation of the left-hand side of the car, we have the side frame at *B*, the pendulum bob at *G*, and the cord at *H*. It will be understood that in every respect the right-hand side mechanism is the duplicate of that on the left. The cord *H* is connected through a spring to the end of a lever *M* pivoted at *N* to a standard *P* erected on the side frame *B*. The lever *M* extends beyond the pivot *N* and at *Q* is pin jointed to an arm carrying a segmental rack *R*. A rod *S* connected to this arm extends backward and passes through a bush carried at the top of a standard *T* fixed to the side frame *B*. On each side of the bush the rod is provided with a spring and a collar. *U* is a pinion which will be referred to later on *V* is a spring which is attached to the lever *M* and the standard *P*, and which serves to keep the cord *H* taut.

Let the car swing over to the right-hand side. The right-hand bob *G* will leave its cord *H* (see Fig. 1) and the left-hand bob will press against its cord. The pressure on this cord (see Fig. 2) is transmitted to the lever *M*, causing the end *Q* and therefore the rack *R* to rise upward. When

Training Wild Animals for Moving Pictures

By Robert H. Moulton

STRONG, ambitious wild animals, that until now have hoped for fame only in the circus or on the vaudeville stage, have found a new field for exercising their talent. A private dramatic school has been established near Fort Lee, New Jersey, which devotes its time exclusively to training beasts for the moving picture stage. Paul Bourgeois, a young French animal tamer, first thought of teaching the jungle inhabitants to appear before the camera, and he immediately founded the school of which he is still director.

This entire institution seems unusual to a regular patron of the "movies." A short distance out of Fort Lee one comes upon a low, one-story building, standing in the center of a small wood. A knock at the door brings M. Bourgeois himself, for he is gratified to show visitors through his unique educational establishment. The door leads almost directly into the studio. This apartment, where the pictures are made, is equipped with a stage, scenery, and skylight, all essential to the operation of any moving picture plant. The animals are kept caged in a large menagerie adjoining the studio, and are taken out only for the daily rehearsals. With a few slight exceptions, the principles of animal posing and human acting are the same. When a film requiring beasts is to be made, the animals are first trained regularly in their simple movements until the performance becomes a habit, since they can respond only to instinct, not to intelligence. Originality must be used by the trainers to make their charges do the right thing at exactly the proper time for the camera man. For this purpose common devices are coating tree branches with honey to keep Bruin aloft the entire length of a scene, or exposing a chicken off the stage when the fox should jump out of a window. The animals feel at home only in the studio of the school, and consequently, the company of human actors must go to Fort Lee when a film is made.

A marvelous circumstance of the profession, for which M. Bourgeois himself can hardly account, is that these so-called dangerous beasts rarely attempt to harm their fellow actors. In fact, no person has been injured by any animal in the New Jersey school. Women, maintains the director, seem even more fearless than men. To prove this assertion, M. Bourgeois describes the production of "Beasts of the Jungle," a popular film at present. In one scene a small, young actress with complete security nestled up close to Princess, a huge tigress, while several stage hands and moving picture employees, with less confidence, nervously held revolvers leveled at the animal.

An interrupted shave. A humerous scene from a wild animal moving picture film.

An Unattended Lighthouse

By H. J. Shepstone

ALTHOUGH every civilized nation possessing a coast line has now a number of automatic light buoys and even beacons, the only unattended lighthouse built on a wave-washed rock boasting of a powerful fog signal and all the apparatus associated with a fully equipped light station is the recently completed Platte Fougère tower, marking the entrance to Russell Channel, which leads to St. Peter's Port, the capital of the island of Guernsey, in the English Channel. The tower guards dangerous reefs which have for years been a menace to shipping, more particularly in foggy weather than at night. The tidal currents and the great rise and fall of the tide, with its swing of 30 feet at this spot, also makes navigation extremely difficult.

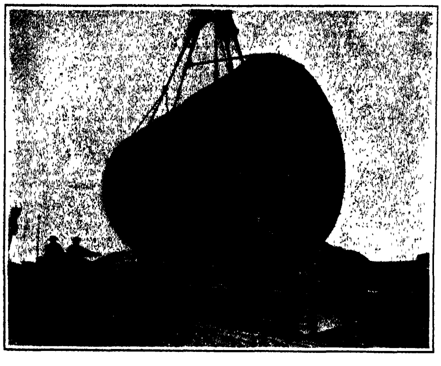
The possibility of erecting a stone tower to accommodate keepers was soon found to be out of the question, not only owing to the great cost that would be involved in constructing a rock lighthouse that men could live in, but also on account of the small area of the rocks. The difficulty was overcome by equipping one of the rocks with an 80-foot tower large enough to hold motors, compressors, fog horn and light, which are all controlled by a submarine cable from the shore. This lighthouse, with its wonderful array of electrical devices for warning and guiding the mariner through the dangerous channel, rises from a rock known as Platte Fougère, always submerged except at low water.

On the entrance level is a compartment containing an electric motor and air-compressor, while on the floor immediately above is a duplicate installation. The syren projects through the top of the tower, the trumpet being so turned as to throw the sounds in a horizontal direction over the water. On the top of the tower is a small automatic acetylene gas plant and lamp. All these devices, many of which are the invention of Mr. E. C. Catford, are controlled from the shore station, 1¼ miles distant, by means of a submarine cable specially made for this work. In fog it is desirable to know that both light and fog signal are working satisfactorily. Accordingly Mr Catford designed special alarms which would inform him of their behavior. At a distance of some 15 feet from the lantern he placed a selenium cell electrically connected with an alarm bell in the shore station So long as the light flashes every ten seconds on the cell the bell does not ring, but should fog obscure the light or the light go out for any reason, the bell at once commences to ring, thus giving the alarm. In the same way a bell rings in the engine room at every blast of the syren. The signal comes instantaneously, the actual sound of the blast itself reaching the shore five seconds later.

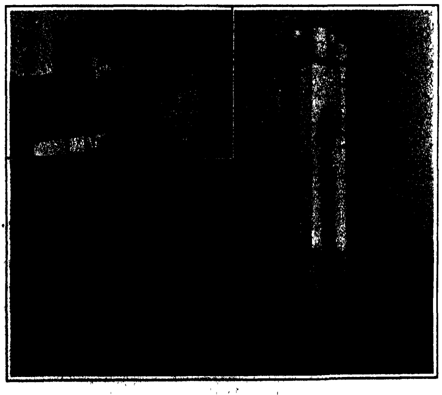
Another device is the telephone which has been installed in the tower for the use of pilots and others. It is the only ocean telephone call office in existence It is principally used by pilots to announce to the authorities the approach of mail boats during foggy weather. They simply climb the ladder of the tower and ring up the exchange.

The shore station is situated at a point known as Doyle Fort. Here a dwelling has been erected for the keepers, adjoining which is the engine house. The machinery includes two oil-engines which drive three-phase alternators, and an air-compressor for working the land syren should that be required. In the tower itself there is a simple switch operated by an electro-magnet, whereby motor-driven air-compressors are thrown in and out of action. Thus, at night the light can be automatically turned on, and at sunrise automatically extinguished. In the same way the fog signal can be set in motion or be discontinued at will.

The cost of the tower and its complete installation was $55,000, which may be considered a small figure when the exceptionally difficult nature of the situation is considered, as well as the powerful nature of the fog signal which has been erected, and the fact that an ordinary rock lighthouse establishment would have cost about $300,000. There is also the saving in maintenance, as only two keepers are required in place of four. Indeed, the Platte Fougère unattended lighthouse has solved a vexed problem how to warn mariners of the presence of dangerous rocks at a minimum of expense



One of the "Britannic's" twenty-nine, 105-ton boilers.



The unattended lighthouse at Platte Fougère in the English Channel. Motors, compressors, fog horn, and light are all controlled by a submarine cable leading to a shore station 1¼ miles distant.

The Boiler Plant of the "Britannic"

THE twenty-nine huge boilers of the 50,000-ton White Star liner "Britannic," now under construction at Belfast, were recently placed in position. Twenty-four of these are double-ended and five are single-ended, all being designed for a working pressure of 215 pounds, which has been found entirely practicable under natural draught conditions. Owing to the "Britannic's" great breadth it has been found possible to arrange five boilers abreast, except in No. 6 boiler room, where, because of the increased fineness of the hull, only four could be placed. All the double-ended boilers are 15 feet 9 inches in diameter, weigh 105 tons each, and are constructed of steel 1 11/16 inches thick. Each boiler has 159 furnaces of the Monson type.

The "Britannic's" boiler installation and the coal bunkers occupy six water-tight compartments, extending for a total length of 320 feet; the engine room takes up 123 feet additional of the 900 feet of length of the ship.

The "Brittanic's" engines, like those of "Olympic," will consist of a combination of two reciprocating engines in the wings, with a low-pressure turbine of the Parsons type placed amidships. The superior economy of this system is due to the fact that increased power is obtained, on the same consumption, by expanding the steam in the low-pressure turbine beyond the limits possible in reciprocating engines. This economy has been proved in the voyages of the White Star liners "Laurentic" and "Olympic"

Iron Ore, Pig-iron, and Steel Production

By Henry Harrison Suplee

DURING the year 1912, according to the report of the United States Geological Survey, the production of iron ore, and the resulting pig-iron and steel, showed a marked increase over the preceding year. The total quantity of iron ore mined amounted to 55,150,147 long tons, or slightly more than 25 per cent more than was mined in 1911, and the amount marketed was about 57 million tons, valued at 107 million dollars.

The amount of pig-iron manufactured during 1912, including the various ferro-alloys, such as spiegeleisen, ferromanganese, etc, was 29,726,937 long tons, which was again rather more than 25 per cent increase over 1911 The amount of pig iron marketed in 1912 was about 30 million tons, having a value at the furnaces of more than 420 million dollars.

Practically all of this iron, together with a small quantity of imported material, was manufactured into steel, the steel production of the United States during 1912 being a little more than 31 million tons, which, at the market price of $28 per ton for steel rails, gives a value of 868 million dollars

These figures show that 107 million dollars worth of iron ore is increased four times in value when converted into pig iron, and more than eight times when transformed into steel, an excellent example of the manner in which human effort adds to the value of natural resources

In order to give some idea of the volumes which these figures represent, we may take the iron ore as weighing 235 pounds per cubic foot, when 57 million tons would occupy a space of 543 million cubic feet, corresponding to a cube with edges 816 feet in length, or a cube higher than the Woolworth building in New York.

When reduced to pig iron, increasing in value four times, the volume becomes about 150 million cubic feet, corresponding to a cube 532 feet high, or nearly that of the Washington monument at the National Capital. The conversion into steel, doubling the value, and raising it from about 100 million to more than 800 million dollars, reduces the volume to about 145 million cubic feet, or a cube 525 feet high

These figures are better grasped by comparison with various large structures, and we may use the new terminal station of the Pennsylvania Railroad in New York. This covers an area of about 450 feet by 850 feet, or 382,500 square feet The iron ore mined in the United States in 1912 would cover this area to a height of 1,420 feet, or double the height of the Metropolitan tower in New York, while the pig-iron would require to be piled in a solid mass 400 feet high to include the production of the past year in America.

It is interesting to note that of the 31 million tons of steel made in the United States in 1912, only about one third was made by the Bessemer process, the remaining two thirds being open-hearth steel Until 1907 the preponderance was in favor of steel made by the Bessemer process, but in that year the open-hearth product equaled that of the Bessemer converter, and it has maintained a steady lead ever since. About 42 per cent of the iron manufactured was produced in Pennsylvania, and 23 per cent in Ohio. Illinois makes 9.7 per cent, while New York and Alabama were close rivals for the fourth place, New York being slightly in the lead

---

More Power from the Rhine.- The amount of power taken from the Rhine for electrical purposes is already considerable, and this is now to be increased by new plants which are to be erected. Starting with the 15,000 horse-power of the Rheinfelden station, two new plants were then put up at Augst and Wyhlen, giving together 30,000 horse-power and distributing current over a large area. But the largest plant of all will be built upon the upper Rhine, and it will furnish no less than 60,000 horse-power, making use of the part of the stream lying between Albbruck and Schäffigen. The new plant is to have 10 turbines of 5,000 or 6,000 horse-power each, and three of the alternators of three-phase type coupled to the turbines will give 5,200 kilowatts, while the other three are rated at 6,150 kilowatts. Such alternators represent the most recent designs for this class of machine, and run at 107 revolutions per minute, working at 6,000 to 6,600 volts. Current will be sent over power lines at 47,000 and 78,000 volts by the use of step-up transformers in the station.

The Latin-American View of the Problem of Our Navy

To the Editor of the SCIENTIFIC AMERICAN:

I am sorry to note that your valued articles dealing with "The Problem of Our Navy" have been brought to a conclusion.

The continuance of such articles is the only way to bring to the mind of the people of the United States that the Navy can be made practical; that it is a school for poor young men who lack educational opportunities; that it gives them a discipline second to none, and most of all, that the first-class policies of the United States, namely, Indivisibility of China, Asiatic Exclusion, the Monroe Doctrine, etc., can only be enforced by a large and strong navy.

This Monroe Doctrine, which has kept many a Latin-American republic from the jealous eye of the European powers, can only be maintained by a navy large and strong enough to make war with the United States a difficult task for these European powers, being as they are, 3,800 miles away from their main naval bases, but with a great preponderance of capital ships—dreadnought type—this task could be accomplished by such powers.

All this you and the Secretary of the Navy have explained wonderfully well in your several articles.

If you were to ask all the more educated class of Latin-Americans what is the object of the great naval programme which Germany has started a decade ago, the answer would correspond with yours: The Monroe Doctrine, the Panama Canal, and her great commercial interests with Central and South America.

I am positive that the better class of Cubans and Latin-Americans are more interested in the increase and efficiency of your Navy than the average inland citizen of the United States. Your Navy is the only friend that we Latin-Americans have that can keep the greedy hands of the nations of the Old World away from us, and dropping fast as she is to a fourth-class navy (not to a third-class as you say), we stand helpless at their hands in the event they should attempt conquest.

I noted in your recent articles that you often spoke of a first-class navy, that of England with forty-two dreadnoughts built and building; a second-class navy, that of Germany with twenty-six dreadnoughts built and building; and a third-class navy, that of the United States, with thirteen dreadnoughts built and building, with France and Japan close behind with eleven and ten of these ships, respectively. Permit me to say that you have not done justice to France. Perhaps it was an oversight on your part. The modern French navy will be, I am sorry to say, superior to that of the United States. I shall make here a *rough comparison* of capital ships built, building, and authorized by both nations:

United States Ships.

	Tons	Main battery.
2 "Michigans"	32,000	16 12-in. guns
2 "Delawares"	40,000	20 " "
2 "Floridas"	43,650	20 " "
2 "Arkansas"	52,000	24 " "
2 "New Yorks"	54,000	20 14-in. "
2 "Oklahomas"	55,000	20 " "
2 "Pennsylvanias"	62,000	24 " "
Total tonnage	338,000	

French Ships.

	Tons.	Main battery.
4 "Jean-Barts"	94,000	48 12-in. guns
3 "Bretagnes"	70,500	30 13.4-in. "
4 "Normandies"	101,548	48 " "
4 (New ones)	116,000	64 " "
Total tonnage	382,048	

Assuming the weight of the 12-inch projectile of the United States and French navies to be 870 pounds; the weight of the 14-inch American projectile to be 1,400 pounds; and the weight of the 13.4-inch French projectile to be 1,433 pounds, in comparing gun power, we see that a single discharge of all the big guns of the 15 dreadnoughts of the French navy would throw a shower of deadly material weighing 245,246 pounds on a target of fourteen American ships, as against a discharge of 159,200 pounds of metal of one single round fired from all the big guns of the fourteen dreadnoughts of the American Navy, on a target of fifteen French ships. This shows a superiority of the French ships of 54 per cent in gun power, regardless of the fact that the projectile of the 13.4-inch gun of the French navy, although of less diameter, has a greater muzzle velocity, and being heavier, is considerably more powerful than the 14-inch American gun. Of these large guns the American ships are equipped with sixty-four, as against one hundred and forty-two on the French ships. It must be borne in mind also that the two "Michigans" have less speed, and that the two "Michigans" and two "Delawares" are not as heavily armored as the four smaller French ships of the "Jean-Bart" type; namely, the "Jean-Bart," "Courbet," "Paris," and "France."

The United States, therefore, stands now as a fourth-class naval power in modern ships. In this *rough comparison* of gun power and tonnage, I have not included the battleships of the pre-dreadnought type, of which the United States has a great superiority, but no nation that looks forward to a first-class line of fighting ships would look upon them for reliance in future naval battles.

My only aim in bringing this comparison to your mind is to show you that as the matter now stands, the United States is dropping as a naval power at a higher rate than it is generally believed in your country, and which is looked at with regret.

Are many Americans also aware of the fact that the Italian government has eight dreadnoughts built and building, and is now considering the construction of four 35,000-ton ships, each carrying twelve 15-inch guns in four triple turrets, the projectile of which guns weighs 1,650 pounds; that the Spanish government has just voted a credit of $324,000,000 for the construction of dreadnoughts, scout cruisers, destroyers, etc.?

I, therefore, encourage you, Mr. Editor, to have this subject of the Navy on your publication every now and then, until you have convinced your people and your country of the necessity to build and keep a *second-class navy*, such as you had in 1906, to maintain peace, not to make war.

Please accept my heartiest thanks for your valued literature, and that of the Hon. Josephus Daniels, Secretary of the Navy, dealing with the subject mentioned above, which is of vital importance to your country, and to all America.

Since I am a foreigner, I must ask your pardon for my poor English. IGNACIO VALDÉS.

Hormiguero, Cuba.

The Tide-predicting Machine

To the Editor of the SCIENTIFIC AMERICAN:

Please grant me space in your journal to make the following statements in reference to a note in your issue of May 2nd, 1914, page 362, headed "The Tide Predicting Machine" and signed by R. A. Harris:

I do not wish to make reply to or discuss the contents of that note. But, in order to prevent silence being interpreted as acceptance of the position assigned me therein, I beg to state:

The C. and G. S. Tide Predicting Machine No. 2 is one of the products of the Coast and Geodetic Survey. The officials of that Bureau are thoroughly familiar with its development from its first inception, prior to 1890 (the year in which Dr. Harris entered the service), to its final completion. They accorded the undersigned the honor to publish a description, under his name, in *Engineering News*, issue of July 20th, 1911, and in the *Journal of the Washington Academy of Sciences*, issue of July 19th, 1911.

The various statements in Mr. C. H. Claudy's article in your issue of March 7th, 1914, are substantially correct, though his references to the undersigned are unduly laudatory. E. G. FISCHER.

Washington, D. C.

The Current Supplement

OUR SUPPLEMENT, No. 2004, brings an illustrated description of the Westinghouse marine turbine.—Dr. F. A. Woods contributes a study on the racial origin of successful Americans.—Prof. G. G. Scott writes on the relation of aquatic animals to the surrounding water.—L. B. Ward gives an account of this year's additions in the United States Navy.—M. v. Jakubowski describes the mining and other methods of obtaining amber on the Baltic coast.—J. J. Smith discusses the power required for refrigeration.—J. H. B. Bryan describes the building of large gas engine flywheels.—In an article on the stability of ships' lifeboats the decked type of boat is recommended, the common type affording little protection even in a fairly good sea.

The Forthcoming Trials of Langley's Machine

LANGLEY'S full-sized aeroplane, on which the United States Government spent more than $50,000, was brought to Hammondsport six weeks ago. In the next number of the SCIENTIFIC AMERICAN we expect to publish a complete illustrated account of these trials from the pen of a special correspondent at Hammondsport.

Our Navy and the Mexican Situation

IN the first of our series of articles on "The Problem of Our Navy," written by the Assistant Secretary of the Navy, the Hon. Franklin D. Roosevelt, we published a map showing the disposition of the ships of the United States Navy on February 12th of this year. This map served to illustrate the fact, which was brought out b~ Mr. Roosevelt in his article, that not only in the stress of wartime, but also in days of peace is our Navy very actively employed. On the day named, there were stationed on the Gulf and Pacific coasts of Mexico, at its various ports, some fourteen or fifteen United States war vessels.

Since the date of that article, the Mexican crisis has become so acute and events have moved so swiftly that, to-day, there are gathered at the various Mexican ports no less than eighty-three ships, in which is included the very flower of our Navy. In this fleet are included eight dreadnoughts, ten pre-dreadnoughts, four armored cruisers, one modern monitor, our three fast scouts, four protected cruisers, twenty-three of our latest destroyers, four gunboats, four third-class cruisers, seven colliers (these the largest and fastest of their class to be found in any navy of the world), one mining ship, two auxiliary cruisers, four large seagoing tugs, one refrigerating ship and six miscellaneous vessels of the auxiliary type.

The events which have led to this great naval demonstration are so well known as to call for no recapitulation here; but we do wish to emphasise the fact, that, when the President, realising that matters between the United States and Mexico had reached that critical line where diplomacy gives way to naval and military force, called for the dispatch of the Atlantic fleet to Vera Crus for the seizure of that port, the Navy was prepared to make a quick response. The Atlantic fleet concentrated on Vera Crus with highly commendable rapidity; the seamen and marines were landed; and before many hours had elapsed, the port was in our possession and the work of disarming the populace, seizing the water-works, and throwing out around the city a cordon of outposts was under way. The work was done with a neatness and dispatch which proved that, for work of this character, our Navy is in a condition of very high efficiency.

The seamen and marines, some six thousand of them, received their baptism of fire under difficult and very disconcerting conditions, the enemy being concealed, for the most part, within houses, or protected by the high parapets of the roofs. Nevertheless, the accounts agree that these young men went through the ordeal with all the steadiness of veteran forces. The severity of the fighting is shown by the fact that on our side alone some twenty lives were lost, and about three times that number were wounded. The Mexicans are estimated to have lost some 200 men.

Following immediately upon the occupation, Admiral Fletcher put in hand the work of restoring order and confidence, with the result that Vera Cruz quickly settled down to its routine of daily life—and this under conditions of security which it had never known in all the centuries of its existence.

We have received a personal letter from the captain of one of our ships, which pays such interesting tribute to the work of the Navy down there, that we venture to publish the following excerpt:

"I have just returned aboard after commanding one of the regiments of bluejackets. The embarkation of the 6,000 sailors and marines was astounding. We passed in review before the Army and Advance Base Marines, and went aboard tugs and steamers. In 35 minutes from the signal to begin moving, the force was clear of the dock and bound back to the ships.

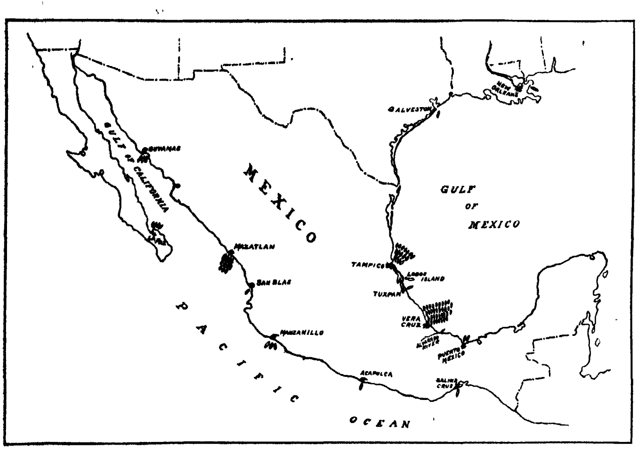
"The Supply Department was beautifully handled by our paymasters and marine officers. The cooking was excellent—meals served promptly—although everything was improvised out of very little in the way of stores and means of cooking. It was a triumph for our Commissary System.

"Our men behaved *absolutely*. We cleaned the city of all firearms, weapons, and ammunition; and we cleaned the streets. What New York, Washington, and Philadelphia need is an effective street-cleaning department such as we put into Vera Cruz, something which our city governments seem to be powerless to organize and keep in *successful* operation."

This fine tribute is in line with Admiral Fletcher's modest praise of the marines and bluejackets, when he said: "In nine days' work Vera Cruz was occupied by the Navy, lawlessness and disorder suppressed, 11,000 firearms taken possession of, and a line of defenses established around the city against an army threatening to recapture it. Business was resumed and normal conditions restored."

Later Gen. Funston reached Vera Cruz with a force of 4,000 men of the Regular Army, which, at the present writing, is in occupation of the city.

For the next few weeks, the center of interest will be found at the Niagara Peace Conference.



Map showing location of the ships of our Navy at Mexican ports on May 20th, 1914.

The Wreck of the Forlanini Airship "Citta di Milano"

FROM the London *Engineer* we glean some details of the disaster which befell the Forlanini airship "Citta di Milano," on April 9th. The disaster is to be attributed not to any defect in design but to the stupidity of the populace among whom the craft was forced to descend. In order to repair a leaky valve, the airship was brought to the ground after she had left her shed, and moored to some trees with ropes partly of hemp and partly of steel, having a breaking strength of five tons. Before the necessary repairs could be made to the valve, the ropes gave way and the ariship was driven for about 170 yards against some mulberry trees. She was again moored, and the commanding officer decided to deflate the bag. A crowd of peasants gathered to watch the operations. The soldiers could not drive them back. Indeed, they could not be even made to give up smoking. As the deflated bag fell over toward the crowd on the left side, several explosions followed hard on one another. A great blast of blue flame shot out from the airship, and passing away left behind nothing but a twisted mass of framework and a struggling body of human beings. About eighty people were more or less seriously injured. Thus through the crass obstinacy of a few yokels a vessel presented to the government by public subscription at a cost of $80,000 was destroyed beyond repair. The airship had had a life of nine months, had made many successful voyages, and like her fore-runner, the "Leonardo da Vinci," had been singularly free from accident.

The Iron Smelter's Fuel Bill

By Henry Harrison Suplee

FEW people realize the magnitude and importance of what may be termed a secondary industry in the United States—the manufacture of coke. The removal of injurious substances, with respect to metallurgical purposes, by driving off the sulphur and other volatile constituents from coal by the operation of coking, forms one of the important elements in the iron industry, since by far the greater portion of the coke made is intended as fuel for blast furnaces used in the smelting of iron ore.

In the year 1912 the quantity of coke made in the United States was 43,983,599 short tons, according to the report of the United States Geological Survey, or in round numbers, about 44 million tons. This corresponds to more than 3,000 million cubic feet, and would fill a cube of 1,442 feet length on each edge, or twice the height of the Metropolitan tower in New York.

The coal from which this coke was made, 65,577,862 tons, would fill 1,311,500 cars of 50 tons capacity, making, if coupled up in one train, a length of 8,700 miles, extending from New York to San Francisco and all the way across the Pacific Ocean.

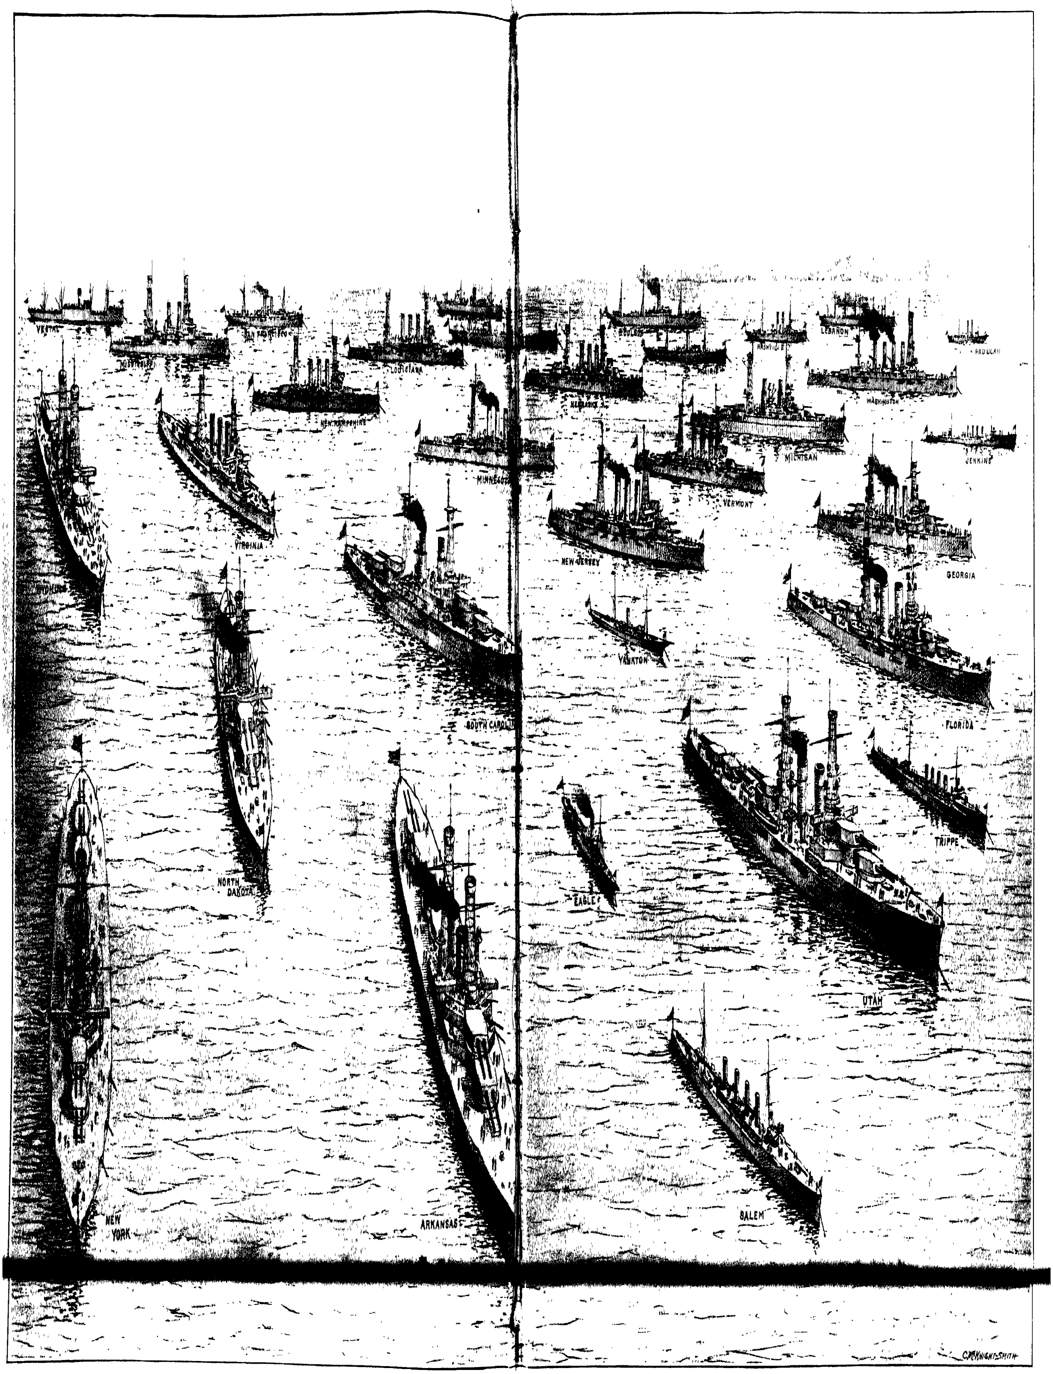
This coal is valued at about 87 million dollars, while the coke made from it was sold for more than 111 million dollars, an increase in value of more than 27 per cent. Less than four years' production of this amount of coke would equal in value the entire cost of the Panama Canal, including sanitation and the purchase price to the French company.

During the year 1912 there was a notable increase in the proportion of coke made in by-product ovens. Formerly all the coke made in America was made in the inefficient beehive oven, all the gas and ammonia going to waste. Last year, one fourth of the entire quantity was made in by-product ovens, the coal being coked in retorts, which enabled these valuable products to be saved, a portion of the gas being burned as fuel for the coking, and a large amount being sold for other purposes. At the present time about fifty million cubic feet of illuminating gas per day is produced as a by-product of coke ovens, supplying such cities as Boston, Indianapolis, Baltimore, and Milwaukee.

From the eleven million tons of by-product coke made in the United States, there was derived sixteen million dollars value of by-products consisting of gas, tar, and ammonia. Since the coke itself had a value of forty-two million dollars, there was added 38 per cent value to the product by the recovery of valuable products formerly thrown away. If efficiency is rightly defined as reduction of waste, there is here a most notable example of modern efficiency. A similar gain, applied to the coke made in the wasteful beehive ovens, would represent more than twenty-five million dollars, without taking into account the greater value in the improved quality of the coke itself. In this connection attention may be called to the emphasis laid by Dr. Diesel upon the efficiency attainable by using gas tar as a fuel for Diesel engines. He maintained that if all coal was refined by coking, the power developed from the gas and the tar would equal that which could be derived by burning all the coal under boilers, while the coke would remain available for metallurgical purposes and such uses as would still require solid fuel.

The South Magnetic Pole

A JOURNEY to the region of the south magnetic pole was made by Lieutenant Bage and Messrs. Webb and Hurley, of the Mawson expedition. Observing stations were established every 10 miles along the journey of 300 miles from Winter quarters, in spite of the extremely rigorous climatic conditions. The readings showed strong local variations in magnetic force, but on an average the dip of the magnetic needle increased about one minute of arc for every 3 miles. From the observations it appears that in December, 1912, the approximate position of the northwestern edge of the magnetic polar area was in latitude 70 degrees 36 minutes S., longitude 148 degrees 12 minutes E. This differs by over 100 miles from the position of the southeastern boundary of the area, as determined by David and Mawson in January, 1909, during the Shackleton expedition. Webb provisionally estimates the width of the area in a SW-NE direction to be about 40 miles. If this estimate is correct, and if the positions were accurately determined in 1909, the polar area must have shifted materially since that time.



BIRD'S EYE VIEW OF THE FLEET OF UNITED STATES SHIPS ASSEMBLED AT VERA CRUZ, ON MAY 20TH, 1914,

The Heavens in June

New Comet Discovered—Counting the Stars

By Henry Norris Russell, Ph.D.

THE second comet to be discovered in 1914 was found by Zlatinsky, at Meitau, Russia, on May 16th, in the northern part of Perseus, almost due north from the Sun. It was unusually bright for a newly discovered comet, being visible to the naked eye, according to the first report, and in an opera glass, according to the next day's telegram. Only the first two days' observations are at hand when this must be written; but they suffice to tell a good deal about the comet.

On the 16th of May it was in 3 hours 18 minutes right ascension and 49 degrees 51 minutes north declination, within a fraction of a degree of the bright star Alpha Persei. The next night it had moved westward by nearly 21 minutes of right ascension, which (in this declination) amounts to about 3 1/3 degrees in the sky, while it had gone northward by but 7 minutes of arc.

Its apparent direction of motion is straight toward Capella, and its rate such that, if moving uniformly, it would reach the neighborhood of the latter star in about six days. At present it is equally well, or ill, to be seen in the evening or morning sky, being some 10 or 15 degrees high in the northwest when the sky grows dark, grazing the northern horizon at midnight, and coming up in the northeast before dawn. For observatories in northern Europe it is circumpolar, and 10 degrees or more high at midnight, so that they have a far better chance of observing it than we have. But in a week or so it will be much higher in the evening sky, and there should be no trouble in observing it.

Nothing can yet be said concerning its orbit, though the facts will be known within another week. But from its rapid apparent motion it can easily be shown that it must be within 75 million miles of the Earth, and not less than 45 millions from the Sun, and also that its motion must be in the opposite direction from that of the Earth.

It may be much nearer to us than the limit just mentioned: but this must remain uncertain until detailed calculations are made. The circumstances are unfortunately such that it is still impossible to say, even roughly, where the comet will be in the sky by the first of June, or even whether it will be brighter or fainter then than at the time of discovery.

Kritzinger's comet has been favorably placed for observation during the present month, and will be almost as well in June. On the 2nd of June its predicted position is in right ascension 20 hours 54 minutes, declination 41 degrees 30 minutes north—about 5 degrees southeast of Alpha Cygni. It is then moving eastward and a little northward, at a little less than 1 degree a day. By a rough extension of the published ephemeris, it appears that on the 16th it should be approximately in 21 hours 48 minutes plus 44 degrees 35 minutes, and on the 30th in 22 hours 30 minutes plus 46 degrees. Its brightness will even then be about two and one half times that at the time of discovery, but as it was then described as fainter than the ninth magnitude, it will not, even at best, be a conspicuous object in a small telescope.

Delavan's comet is slowly coming out into the morning sky, but is not observable yet. Its position on June 18th is given as 4 hours 28 minutes plus 26 degrees 12 minutes, which would make it rise 1 hour and 20 minutes before the Sun. It will be observable once more in July, but will not become conspicuous till later in the year.

It has been customary to comment here upon the astronomical literature of the past month; and for mention this time we may well take one of the numerous pieces of good work which are now coming from the University of Lund, in southern Sweden, where Prof. Charlier has gathered around him a group of able students.

Fortunately for astronomers in most countries, these publications, though bearing the title, "Meddelanden fran Lunds Astronomiska Observatorium," are written sometimes in German, but often in excellent English, as is the case with the work under consideration by Dr. Hans Henie.

Dr Henie has set himself the problem of determining the number of stars in the sky brighter than the eleventh magnitude, and the density with which they are distributed, per square degree, in the various parts of the heavens.

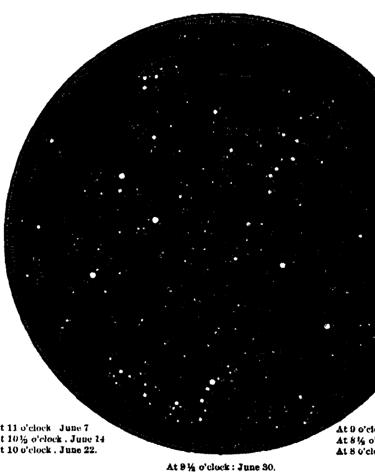
As material for his investigation, he employed the well known "Harvard Sky," a series of fifty-five plates, taken at Harvard and Arequipa, Peru (which among them cover the whole heavens from pole to pole), of which duplicates have been furnished to many observatories.

The first thing to do was to count the number of star-images shown on these plates. Dr. Henie ingenuously remarks: "As the number of stars was about one and one half millions, I refrained from counting them all." Instead of this, he mapped out a series of one hundred squares, one centimeter on a side, distributed evenly over each plate, and covering about one quarter of its area, and counted the stars in these squares. The average number of stars per square was 78, and the whole number of stars counted no less than 425,497. In one region in the Southern Cross, nearly 2,000 stars were counted in a single square.

The next problem was to find out how faint were the faintest stars shown on each plate. This was made relatively easy by the fact that, in the regions of the sky surrounding a large number of variable stars, the brightness of a sequence of faint stars has been measured. By identifying these stars on the plates, the magnitude of the faintest stars visible could at once be determined. But this was not the whole story, for it was found that much fainter stars were shown near the center of each plate than at its edges, and corrections had to be made for this, which was successfully accomplished by a very ingenious method. After this has been done, the number of stars in each region which are brighter than the eleventh magnitude can be calculated. Dr. Henie finally concludes that the whole number of stars in the sky above the eleventh magnitude is 1,013,328, or an average of not quite 25 per square degree, which is equivalent to a little more than five such stars in an average bit of sky as big as the full Moon. But the number of stars per square degree varies enormously in different parts of the sky. The regions poorest in stars are in Ursa Major, in about 9 hours plus 50 degrees, and again in about 13 hours 30 minutes plus 57 degrees, in each of which there are less than five stars per square degree brighter than the eleventh magnitude. The whole region occupied by the Great Dipper (which lies between the two positions just mentioned) is very poor in telescopic stars.

The richest regions are in Ophiuchus in 18 hours 20 minutes plus 2 degrees, where there are actually 112 stars per square degree above the assigned limit of magnitude, and in Cygnus (21 hours 8 minutes plus 52 degrees) with 105 stars per square degree. Regions almost as rich are found in Sagittarius (17 hours 40 minutes minus 27 degrees) and Argo (9 hours 40 minutes minus 62 degrees). All these rich regions lie in the Milky Way, while the poor ones are near its pole. The average number of stars per square degree in the Milky Way is more than forty, while near its northern pole it is about seven. Near the southern galactic pole, curiously enough, the number of stars per square degree is about twice as great.

There is little doubt that if similar counts could be extended to still fainter stars, the increase of their numbers toward the Milky Way would be still more marked.



At 11 o'clock June 7
At 10½ o'clock . June 14

NIGHT SKY: JUNE AND JULY.

The Heavens.

The rich regions of the Milky Way, of which we have just been speaking, are now conspicuous in the eastern and southeastern sky, though the vast agglomerations of still fainter stars which form the great clouds extending from Aquila to Scorpio are even more prominent. Among the brighter stars, too, many of the finest groups will be found in this region; Cassiopeia, low in the northeast; Cygnus and Lyra, a little north of east; Aquila, farther to the southward; and then Sagittarius and Scorpio, the latter extending to the meridian. Ursa Minor and Draco are in the north, above the pole. Hercules and Corona are right overhead, with Ophiuchus and Serpens to the southward. Arcturus shines splendid, high in the southeast, and Spica, apparently fainter, but far more remote, and really brighter, appears below. Leo is low in the west, and Ursa Major well down in the northwest, and sinking steadily.

The Planets.

Mercury is an evening star all through June, and is well observable in the earlier half of the month, setting at about 8:45 P. M. on the 1st and 9:10 on the 18th, when he is at his greatest apparent distance from the Sun. After this he moves southward, and becomes less easy to see; setting about 8:30 at the end of the month. On the 1st he is brighter than Arcturus; but as his crescent narrows he grows fainter, and by the end of the month he is fainter than Regulus.

Venus is likewise an evening star, setting about 9:30 all through the month, and is very conspicuous.

Mars, too, is visible in the evening, but is higher in the sky, setting about 11 P. M. on the 15th. He has fallen off very much in brightness, and is now no brighter than the brightest stars of the Great Dipper.

Jupiter is still a morning star, but is growing more conspicuous. He is in the eastern part of Capricornus, and rises near midnight on the 1st, and a little before 10 P. M. on the 30th.

Saturn is in conjunction with the Sun on the 13th, and cannot be seen this month.

Uranus is in the middle of Capricornus, and rises about 10:15 P. M. in the middle of the month. Neptune is in Gemini, and sets at about 9:30 P. M. on the same date.

The Moon is in her first quarter at 9 A. M. on the 1st, full at midnight on the 7th, in her last quarter at 9 A. M. on the 15th, new at 11 A. M. on the 23rd, and returns to her first quarter at 2 P. M. on the 30th. She is nearest us on the 5th, and farthest away on the 17th.

While traveling around the skies, she passes near Uranus on the 11th, Jupiter on the 12th, Saturn on the 22nd, Mercury and Neptune on the 25th, Venus on the 26th, and Mars on the 27th.

At 2 A. M. on the 22nd, the Sun attains his greatest northern declination, 23 degrees 27 minutes 10 seconds, and enters the "sign" of Cancer, which, being an imaginary region of the ecliptic and affected by precession, has during the last 2,000 years backed into the constellation Gemini, and, as the almanacs will have it, "Summer commences."

Princeton University Observatory.

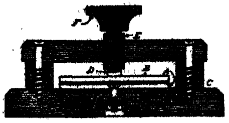
Guinea Pigs were imported into this country for laboratory experiments during the year ended June 30th, 1913, to the number of 12,112, as compared with only 1,471 the year before.

A Variable Condenser

By Frederick E. Ward

IN constructing his own wireless receiving apparatus, the average amateur probably encounters his greatest difficulty in making a good variable condenser, because the commercial form of this instrument, consisting of a system of fixed and of movable vanes, requires that a large number of parts be made and assembled with considerable care.

To overcome these difficulties the author has developed the simple form of condenser shown in section in the accompanying drawing, where *A* and *B* represent the condenser plates, which are two brass disks about 3/32 inch thick and 2 inches in diameter. The first of these plates is fixed to the frame *C*, of wood or of other suitable insulating material, by a machine screw and nut which also serves as a binding post. The other plate is attached to the screw *D*, passing through the nut *E*, and carrying at its upper end the insulating knob *F*, by the turning of which the top plate is adjusted up or down, thus taking advantage of the law that, other things remaining constant, the capacity of a condenser is inversely proportional to the distance between its plates.



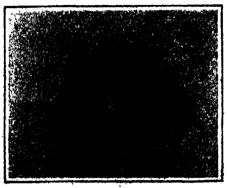
Constructional details of the condenser.

In making the simple form of variable condenser just described, it should be borne in mind that the best results are to be obtained by the use of a screw of fine pitch and of large diameter, such as is used in the well-known micrometer caliper. Not less than forty threads per inch, with a diameter of ¼ inch, is recommended. Care should be taken that the nut and screw are a reasonably good fit, and that the upper disk be turned off in the lathe so that its face will be truly at right angles to the axis of the screw. The lower disk should be leveled up by shims of tissue paper, if necessary, so that the two disks meet squarely when screwed together.

When the condenser is to be used in series with a large receiving aerial, for shortening its natural wave-length, it is of advantage to have nothing between the disks but air, for then they can, on occasion, be conveniently screwed together and short-circuited. If, however, *the condenser is to* be used in parallel with receiving instruments, where a short-circuit would be undesirable, this mishap may be guarded against by laying between the disks a slightly larger disk made from a film of clear, white mica one thousandth of an inch thick. This mica film has the effect of multiplying the maximum capacity of the condenser by a factor of about six.

In the photograph is shown a well-made instrument of the type just described. This one has a top piece of brass supported by four hard rubber posts, through which pass the four machine screws by means of which it is fastened to the base. The adjusting screw is provided with a graduated thimble so that the distance between the plates can be read off as with a micrometer, this serving as a scale. The knob could just as well have been provided with a hand or pointer moving over a scale marked on the top plate.

Such an instrument is suitable for use in a wavemeter of the Doenitz type, for which purpose it has a slight advantage over the usual form of condenser in that its capacity increases rapidly toward the end of the scale where the plates come together, while in the *ordinary form* the capacity varies uniformly along the scale. Since it is desirable to calibrate the scale directly in wave lengths, which are proportional to the square roots of the capacities, the disk type condenser, therefore, gives more nearly uniform scale divisions.



Home-made variable condenser.

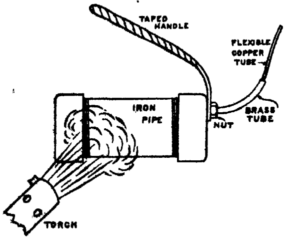
The maximum capacity of the average commercial type of variable condenser is about 0.003 microfarad. The calculated capacity of a pair of 2-inch circular plates spaced one thousandth of an inch apart in air is only about 0.0007 microfarad, but this value is increased to about 0.0045 microfarad by the introduction of a mica film, as recommended. In either case unscrewing the plates until they are 0.01 inch apart reduces the capacity to about 0.00007 microfarad. It will be seen from these figures that 2-inch disks are large enough to serve a useful purpose in many cases, though larger plates may often be employed to advantage.

Construction of an Oxygen Carbon Remover

AN oxygen generator for removing the accumulation of carbon from the combustion chamber and the piston of an internal combustion engine may be constructed as follows:

Take a short length of wrought iron pipe 1¼ inches in diameter, and thread and cap it at either end. Through one cap drill and tap a hole to receive a length of brass tubing. Solder a suitable length of annealed copper tubing into the end of the brass pipe. A handle may be provided by fitting in position a piece of ¼-inch strap iron, drilled for the passage of the brass tubing, and securing it with a nut as is shown by the sketch. The handle should be taped.

To use the device, a couple of ounces of chlorate of potash, to which has been added a teaspoonful of manganese dioxide, the two being thoroughly incorporated, are introduced into the chamber formed by the pipe, the rear cap being removed for the purpose. After the cap has been screwed tightly in place again, the chamber is heated with a blow torch and the end of the flexible copper tubing is introduced into the combustion chamber of the motor. As soon as the ingredients are sufficiently heated, oxygen is given off and the heat should be kept constant to insure a steady flow. In the presence of the oxygen, the caked carbon can easily be ignited and will burn from the surfaces in a minimum of time. Care should be taken not to apply too much heat. For cleaning multiple cylinder motors, the quantities of chemicals can be increased. Since the manganese dioxide acts merely to stimulate the decomposition of the potassium salt, it is evident that the proportions are not all important. Both chemicals can be obtained from any chemist in *small quantities, and at low cost.* Care should be exercised to keep foreign substances from contact with the chlorate of potash.



Oxygen generator for removing carbon from pistons and cylinder.

Dangers of Aviation.—In an interesting volume by Roger Depaginat on the martyrs of aviation, some interesting statistics are given showing the progress accomplished from 1908 to 1912. The total number of aviators for each year is given, together with the total distances traversed in the air. The price paid in lives for these triumphs is also given.

Year.	Aviators.	Miles Traversed	Killed
1908	5	1,500	1
1909	50	40,000	3
1910	500	920,000	29
1911	1,500	3,000,000	78
1912	5,800	17,000,000	140

Another table is attached showing the advance made per life lost.

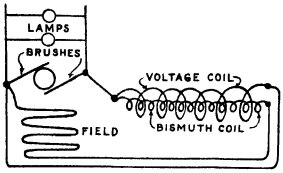
1908 one killed for 1,500 miles of flight.
1909 one killed for 14,000 miles of flight.
1910 one killed for 32,000 miles of flight.
1911 one killed for 40,000 miles of flight.
1912 one killed for 120,000 miles of flight.

Thus, from 1908 to 1912, the number of fatal accidents has proportionally diminished from 100 to 1, if one considers distances traversed, and from 10 to 1, if one considers the number of aviators flying. At this rate aviation will soon be less dangerous than automobiling.

Automatic Voltage Regulator

By J. Naveman

THE writer recently installed a shunt-wound dynamo on a motor car to supply current for lighting purposes, the drive of the motor being taken directly off the cooling fan pulley. However, the regulation of the output at the varying speeds offered a serious problem.



Automatic voltage regulator.

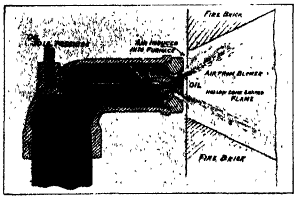
The resistance of bismuth increases when it is placed in a magnetic field, and the amount of increase varies directly as the strength of the field, within certain limits. Forearmed with this knowledge, the regulator shown by the accompanying sketch was constructed. A coil of bismuth wire was placed in series with the field of the dynamo, and the bismuth coil was made the core of a voltage coil which was connected across the lamp circuit. Under these conditions, the bismuth was subjected to the fluctuations of the voltage as indicated by the varying strength of the magnetic field of the voltage coil, and the resistance of the bismuth varied accordingly. When the voltage rose, due to increased speed, the field strength and resistance increased in proportion, cutting down the strength of the field circuit.

The chief difficulty lay in forming the bismuth coil, since that metal is too brittle to be drawn to a filament. It was solved by embedding a long, loosely coiled steel spring, previously oiled, in plaster of Paris, and, after the material had set, unscrewing the spring from the plaster. The bismuth, molten of course, was forced into this mold with the aid of a dentist's vacuum casting machine. When the plaster was carefully broken away, a perfect coil of the desired metal was left.

Low-pressure Atomizing Burner

OIL burners using high-pressure air or steam have been predominant ever since oil has been used as a fuel, owing to the difficulty of atomizing the oil with low-pressure. The typical low-pressure burner merely projects into the furnace a core of oil surrounded by a column of air, which on striking an abutment in the furnace causes an admixture of the oil and air.

The atomizer here illustrated embodies some radical improvements designed to convert the oil into a fog or mist. It comprises an inner nozzle through which the oil is delivered from under a high pressure. The passage-way in this nozzle is terminated, at the delivery end, by a small orifice, and within this passage there is placed a spiral. The oil is guided around this spiral, effecting a violently whirling jet in the orifice, which action causes it, upon delivery, to spread out in a cone-shaped film. Surrounding this nozzle is a casing, inclosing a large spiral, through which the air (or steam) must pass, so that the air, too, is delivered from the final restricted discharge orifice in a whirling current, which action likewise causes the air to assume the form of a hollow cone-shaped film. The oil film is drawn into the whirling current of air, and, being the heavier fluid, the centrifugal force throws it toward the outer edge of the air film. The air from the blower therefore penetrates the mechanically atomized film of oil and reduces it to a fog. This action results from blower air of under 8 ounces pressure, giving a high degree of atomization at low cost and a mixture which affords perfect combustion without an excess of air.



Low-pressure atomizing burner.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

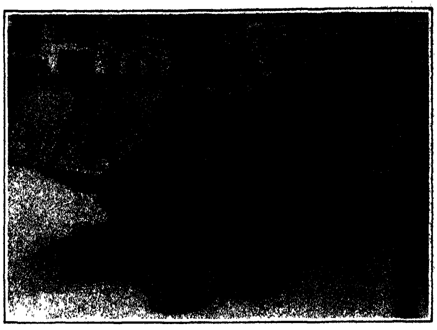
Dumping Truck for Ash Removal

By Ross Babcock, M.E.

THE removal of accumulations of ashes and other refuse always has constituted more or less of a problem in large cities. Now, however, the municipal authorities of Greater New York would seem to have solved the problem in an effective manner. There just has been placed in service a new type of motor-propelled and dumped vehicle which takes the place of no less than 15 to 20 horse-drawn carts of the usual type. It is shown by the accompanying illustrations.

The new truck is not like anything else of its kind. It has an underslung frame, and the sides are so arranged that it never is necessary for those loading the vehicle to lift ash cans more than waist high. The truck will hold about 120 cans of ashes. The body itself, which is made of steel, is 13 feet 3 inches long and 7 feet 6 inches wide, the rated capacity being 252 cubic feet. Both the sides and the top are removable sections. The dumping mechanism is operated by the motor and in the hoisted position the body rests at an angle of 53 degrees. Thus, the load can be dumped at any prescribed spot, or may be slid directly into the scows used for such purposes.

The truck now has been in use for some time, making the haul to the dumping ground—a run of about three miles—in 14 minutes on the average. One man drives the truck and operates the dumping mechanism, and as it has a capacity equal to five of the ordinary horse-drawn carts, the saving in operating expenses is material.



The ash cans need be lifted only waist high.

The load can be dumped at any prescribed spot.

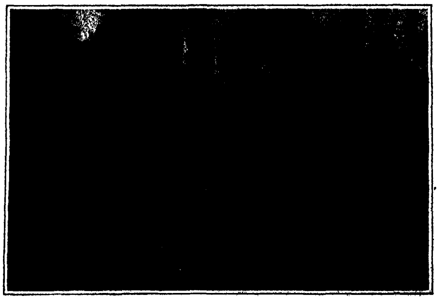
Road Structure and the Commercial Car

By K. G. Martin

COMMERCIAL car manufacturers should come to an appreciation of the very great need for concerted and definite action on their part in the matter of modern road construction.

Those who have to do with pleasure vehicles have from time to time evinced some interest in the matter and we have, of course, our good roads associations. There has been lacking, however, that knowledge and desire for knowledge among the builders and users of modern trackless freight carriers regarding road structure that constitutes so essential a forerunner to combined and effective effort.

Undoubtedly by far the greater field for the motor truck lies in our rural districts, and it is here that the greatest work is to be done in putting upon a scientific and commercial basis road building on a large scale, and just so energetically as the truck-makers fight for good roads just so quickly will come their returns from this almost virgin field. We hear much of service stations and the like, but is it not the part of really worth-while service to be constructive in its nature, and to endeavor to improve and perfect the road surfaces over which the road vehicles are to travel? It would seem so, for notwithstanding all the care and effort put into the design and construction of a commercial motor car, the forcing of it over badly paved highways at commercially necessary speeds will bring about its disintegration in an alarmingly short time. It is not too much to say that the ratio of the weight of the empty truck to the weight of the load it will carry could be greatly reduced if it were known that it would not be required to so fashion the structural members—frame, ties, struts, axles, wheels, etc.—that they must be able to withstand without fracture or permanent distortion many times their ordinary working stresses.



Unretouched photograph of road surface, showing disintegration of the top layer due to flow under traffic.

Another and most important phase of the truck question, and one that affects the utility of this up-to-date beast of burden to a marked degree, is the matter of speed. It is not alone to its surefootedness, freedom from sunstroke, rapid acceleration and deceleration, that the vogue of the motor-wagon is due, but in a very great measure to the saving of time effected through comparatively higher speed. The higher the speed can be pushed the greater will be the saving. Why, therefore, is the speed of motor trucks held to-day within such low limits? We know that outside of "joy riding" and "scorching," and barring drunken and otherwise palpably unfit drivers, that increased speed in motor travel does not mean a proportionate increase in the number of accidents.

But the speed of commercial cars is strictly limited in the majority of cases, either through gearing or through direct engine control, so that the driver cannot exceed a certain predetermined maximum rate. Evidently the speed limitation is set by the manufacturers, who have learned by their own experience, or by that of others, at what speed their vehicles can travel over the poorest road conditions to be encountered without a total collapse.

The methods of road work in the United States and in Europe are dissimilar in many respects, the point of differentiation most interesting to us being the feature of maintenance. Roads are built in this country—and rebuilt. They are constructed sometimes with exceeding care, and are then neglected until they have been so far disrupted and broken that they not only cease to serve as highways, but are even unfit to form the foundation of a new road surface, and have to be entirely rebuilt.

We can and do build good roads, but we do not take care of them. Maintenance, as understood and practised in France, for instance, is non-existent in this country. France has undoubtedly reached the high-water mark in roadways, and its main thoroughfares are a delight to behold and a joy to travel over, and there is absent that only too well-known feature of American touring—fifteen miles of perfect roadway, hard as nails, dustless, beautifully cambered, with just the proper heel at the curves—then, five miles of broken stone, soft fill, steam rollers, and fresh tar oil.

In cities, where the pavements are being constantly disturbed for the repair or extension of subsurface utility structures, and the original tenacity and combined resistance of the surface and foundation are impaired, both as regards their immediate relation, and the relation of that particular section to the surrounding and adjacent roadway, it is not surprising that sinks and pits develop. But in the suburban or country roads of either the plastic or pressed dirt type, it is often difficult to account for the holes that occur. As a rule, these can be traced to an original minute flaw or abrasion that, in the absence of the constant inspection and replacement that should prevail, develops under the pound and rack of traffic into an ever widening and deepening opening. Occasionally they can be traced to a cut or break caused by the solid rubber or steel-shod wheel of a heavy vehicle. This has led some people to suggest the strict limiting of the weight of commercial motor cars that may be operated over such roads, but it would seem rather that the roads should be built to stand the traffic.

There is one element of road disturbance which should merit attention from the truck-maker, as it has developed since the motor truck has come so largely into use. It is the "flow" of road surfaces under the influence of heavy traffic, and reaches its most noticeable and destructive form in city streets where the traffic is unidirectional. If a grade exists, the effect is intensified. In the case of an asphaltic or plastic covering the surface is stretched and forced down the grade to some point where the resistance is sufficient to withstand the pressure exerted by the rolling-out action of the wheels, and at this point the surface is forced into ripples and billows that are soon cut in their turn into ruts and holes. In the case of rectangular creosoted wooden or asphalt composition blocks there can, of course, be no such rolling out of the blocks, as they move

(Concluded on page [illegible])

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the Scientific American.

Aeronautics.

PYROTECHNICAL ILLUMINATING DEVICE.—E. Hyra and K. [illegible], Vienna, Austria-Hungary. The invention provides a pyrotechnical luminous body which will be automatically ignited when dropped from an aircraft. The frame carrying the luminous body is capable of receiving a written communication and the luminous body will indicate the place where the manuscript rests when it reaches the ground.

Pertaining to Apparel.

HAT FASTENER.—G. A. Ulrich, City of Mexico, Mexico. An improved method of holding hats on the head is provided by this invention. The hat is furnished inside with combs which are pressed by a spring member into the hair, but which may be withdrawn from the hair, when it is desired to remove the hat, by means of pins secured to the combs but extending to the outside of the hat.

BLOOMER SKIRT.—M. Langman, 47 Elton Street, New York, N. Y. This bloomer skirt is especially adapted for use when exercising, skating, swimming, riding or the like, and is arranged to permit free movement of the limbs. It consists of bloomers with integral overlapping front flaps and rear flaps which may be fastened together to provide a skirt effect.

HAIRPIN.—H. Jacobsen, Address Ardon B. Judd, care of Capps, Cantey, Hanger & Short, Fort Worth, Texas. It has been found that the ordinary hairpin of the bifurcated type when not securely placed in the hair is very likely to jar or slip out and be lost. To obviate this, the present invention provides the hairpin with means for gripping the hair so that it will remain in place.

HAIRPIN WITH HAIR-LOCKING MEMBER.

Electrical Devices.

FIRE ALARM CIRCUIT CLOSER.—B. Trent, 50 Chester Avenue, Clifton, N. J. The invention provides in connection with a pair of conductors forming a part of a fire alarm system a third conducting member held inoperative by a fusible connection, so that in case of fire this connection would melt, releasing the conductor and permitting it to drop upon and make contact with the two line conductors, thereby sounding the alarm.

Of Interest to Farmers.

PLOW.—O. L. K. H. Oldenburg, Mount Moriah, Natal, South Africa. This invention provides a plurality of plow shares and mold boards mounted on a shaft adapted to be rotated, the boards being curved in the manner of a screw propeller blade, so that they will cut the ground and turn it over thoroughly, one mold board extending beyond the vertical plane of the land side of an adjoining plow member to work more thoroughly the surface of the ground between the end plow members on the shaft.

Hardware and Tools.

WRENCH.—J. H. Kuhns, address Curry & Spillers, Tulsa, Okla. This improvement provides a wrench for use in any work, especially for turning pipes and other cylindrical objects, wherein the movable and fixed jaws are connected by a rack and gear wheel, and wherein a pawl is provided for locking the gear wheel from rotation to hold the jaws in fixed position.

NOZZLE.—H. Birnbaum, Rapid City, S. D. The object here is to provide a nozzle which will permit of the discharge of various sized streams therefrom, and which may be readily and quickly adjusted to vary the size of the stream, and a further object is to provide a nozzle with means whereby a spray may be discharged along with any of the streams of water when it is so desired.

Heating and Lighting.

OIL-BURNER.—W. T. Dowling, Delia, Kansas. This oil burner is adapted to be used in stoves, and comprises a base having a pan at one side for oil to start the burner and a gooseneck leading from the open base and terminating in a bell over the pan. The air and fuel enter the burner in the top of the bell. After the burner has been started the flame burns around the mouth of the bell.

STOVEPIPE SHIELD.—E. Gies, Mount Angel, Ore. This shield serves to protect adjacent walls, buildings, trim, furniture, and other structures from injury by heat emanating from the stovepipe or other element with which the shield is employed, which can be readily mounted in position and as readily taken down, which comprises a plurality of interchangeable sections which may be of any desired number, and which requires no structural change in or addition to the stovepipe with which it is employed.

HOT-AIR FURNACE BONNET.—W. F. Daw, care of the Wilbur E. Steele Co., Hartford, Conn. The bonnet is made of parts so designed that the bonnet can be shipped from manufacturers or jobbers in collapsed form to the point of installation, as the parts can be readily locked or fastened together without special machinery or particular skill to form the complete bonnet for application to the body of the furnace.

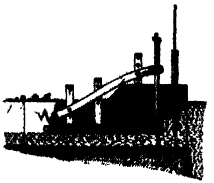
CONTROLLING DEVICE FOR WATER-HEATING SYSTEM.—J. E. Goodwin, 80 Walnut Ave., Norwood, Mass. To eliminate expansion pipes in water-heating systems this invention provides a casing having two valve-controlled communicating openings, one being a relief valve and the other a pressure reducing valve. The device is easily accessible for inspection and causes a quicker circulation of water, therefore permitting a reduction in the size of the pipe.

Of General Interest.

AIR TANK.—W. V. Garceau, Grand Rapids, Mich. This improvement relates to tanks and more particularly to compressed air tanks, the purpose of the invention being to provide a compressed air tank in which, under suitable conditions, the body portion of the tank expands and contracts according to air pressure carried—or in other words, according to the amount of air contained in the tank. The invention is of special service where lightness combined with small volume and freedom from mechanical complications is desirable.

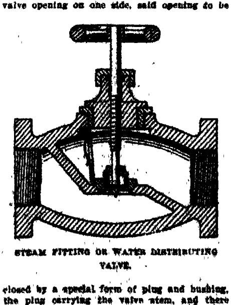
AIR TANK.

CONTROLLING DEVICE FOR WATERWAYS.—W. L. Hurst, Box 572, Aspen, Colo. This inventor provides a device for use in irrigating ditches and other waterways, and arranged to automatically regulate the volume of water flowing through the ditch under normal conditions, to keep the controlling device automatically free of accumulating trash and other extraneous matter, and to automatically close the waterway in case of a flood.



CONTROLLING DEVICE FOR WATERWAYS.

VALVE.—J. A. Wilson, 18 Abbott St., Detroit, Mich. The primary object of this invention is to provide a valve body having a valve opening on one side, said opening to be closed by a special form of plug and bushing, the plug carrying the valve stem, and there being provided a pivoted check valve adapted to close automatically against the inner edge of the bushing when the valve is removed.



STEAM FITTING OR WATER DISTRIBUTING VALVE.

SALES DEVICE.—F. W. DeWitt, Box 286, San Francisco, Cal. In dry climates it is difficult to sell cigars from the top of counters because they dry out very quickly. Accordingly, Mr. DeWitt has invented a device consisting of a series of jars in which the cigars are held for display, and which may be individually uncovered, and tilted toward the customer by the operation of finger keys.

UMBRELLA-PROTECTOR.—H. C. Anderson and A. P. Kemmer, 2461 Frisby Avenue, Westchester, New York. The invention provides an insulating and cushioning protector for the tip of the umbrella rod to protect the person carrying the umbrella from the effect of shocks from electricity and to prevent injury to the joints and catches of the umbrella when it is used as a cane.

CASTING OF IRON.—I. E. Lester, 44 Sandwell road, Handsworth, Birmingham, England. The object of this invention is to provide simple and reliable means for imparting a hard surface to an iron casting for the resistance of wear, while retaining that toughness in the body of the casting which is necessary for the resistance of stresses liable to cause fracture or breakage.

HALTER.—R. Scott, care of Harvey B. Dick, 329 Second Ave., East Kalispell, Mont. Mr. Scott's invention relates to halters, and it has for its object the provision of one having two parts of tubular steel which telescope, and which are normally positioned on the horse below his eyes, straps being provided for holding the tubular steel parts in place.

Machines and Mechanical Devices.

FIRE FIGHTING APPARATUS.—S. H. Willis, 582 Broome St., New York, N. Y. This invention provides a mechanism to support a fire hose at an elevation for fighting fires, the nozzle being manipulated to play the water on the fire in simulation of manual manipulation; and provides a supporting mechanism upon an extension ladder with nozzle manipulating means operable from the foot of the ladder.

PROCESS OF STERILIZING AND PACKAGING RICE.—W. S. Davis, Jr. Address Seaboard Rice Milling Co., Galveston, Tex. The shaker, the bin, the packaging machine, and the cartons are covered and protected, preferably by sheet metal hood or hoods, so that fresh or cool air is prevented from access to the heated rice from the point of its discharge from the drier to its delivery and sealing in the package, whereby the cracking and breaking are effectually avoided.

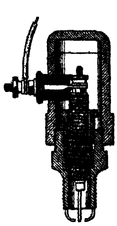
LIQUID MEASURING DEVICE.—E. A. Apfell, 793 E. 168th St., Bronx, N. Y. The object here is to provide a liquid measuring device for measuring liquids periodically drawn from a barrel or other container. As the amount of air passing into the container by the way of the liquid measuring device is the same as the amount of liquid withdrawn, it follows that the amount registered by the registering end indicates the amount of liquid withdrawn from the container.

CLEANING AND SCOURING ATTACHMENT FOR METAL ROLLS.—J. Dunlop and J. D. Davidson. Address the former, 909 Center St., Wellsville, Ohio. This invention is particularly intended for cleaning and scouring the surface of metal rolls used for rolling steel plates or sheets. The apparatus used is automatic and produces a roll face which is smooth and uniform, steel sheets being rolled flat, without stopping the normal operation of the mill, so that an important economy and perfect mechanical result are effected.

ROPE CLAMPS.—S. E. Ryder, 817 N. J St., Muskogee, Okla. The improvement is on that type of rope clamps whose chief parts are a frame, jaws or clamps proper hinged thereon, and a screw relatively connecting the outer ends of the clamp arms which project laterally from the jaws, so that by rotation of the said screw, the jaws may be clamped upon the rope with any required degree of pressure.

Prime Movers and Their Accessories.

SPARK PLUG.—J. DeL. Barmore, Box 316, St. Vincent Island, Apalachicola, Fla. A contact member is provided which is surrounded except at the ends with an insulating material, and is clamped or connected with a supporting screw member which is designed to be secured into the cylinder of an engine, and to which is secured by suitable threads a protecting housing. A water-tight insulating member is provided for carrying the wire into the contact member so that a plug can be used at any desired place even though the same is submerged in water.

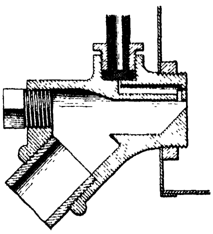


SPARK PLUG.

ROTARY VALVE.—C. H. Bantley, Lebanon, Mo. Use is here made of a rotary admission valve and a rotary exhaust valve, each valve consisting of two revoluble valve cylinders, one within the other and rotating in opposite directions, the valve cylinders having ports adapted to register with each other, and at the same time with a corresponding cylinder admission or exhaust port.

Railways and Their Accessories.

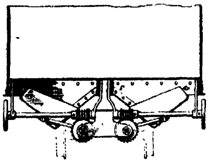
TRACK SANDER.—J. H. Watters, Augusta, Ga. Mr. Watters' invention has for its purpose to provide a track sander, simple in construction, the sander having an air jet which is disposed to discharge the air against an inclined bottom member serving to direct the air together with the sand to an outlet disposed below the inclined bottom member. As there is practically no blasting against the sander casting proper there is little, if any, cutting action.



TRACK SANDER.

STATION-INDICATOR.—C. S. Emery, 713 South 20th St., Birmingham, Ala. This station indicator is adapted particularly for use on street cars to indicate to the passengers within the cars the various streets as they are reached. The indicator is actuated by plugs located on the tracks which engage a tripping member connected by suitable gearing to the indicator.

DUMP CAR.—J. D. Mettler, Snydertown, Pa. This inventor provides a car having hinged bottom portions which may be easily moved to effect the dumping of the contents of the car, especially coal, and which may be readily secured to hold the load without any danger of dumping the same in transit. He provides a device having means for draining water from the load, and at the same time preventing leakage of portions of the material which is being transported.



DUMP CAR.

Pertaining to Vehicles.

TIRE.—R. E. Sturman, Delano, Minn. The purpose in this case is to produce a tire which will have all the advantages in the way of resilience that are obtained by the use of pneumatic rubber tires, and which will in addition be more expansive than tires of the pneumatic type referred to.

Designs.

DESIGN FOR A LOVING CUP OR SIMILAR RECEPTACLE.—W. H. Head, Hookset, N. H. The cup comprises a standard and a bowl shaped like an inverted cone. The bowl is provided with three handles, and there are six spoon-shaped ornaments symmetrically disposed about the cup with the bowls of the spoons clustered about the upper part of the standard.

NOTE.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

A Vital Need of Big Business

The exclusive features of Firestone Truck Tires and Rims answer the business need for Most Mileage, Continuous Operation and Low Maintenance Cost.

Yet Firestone superiorities are yours at only ordinary prices because of greatest volume of production in America's largest exclusive tire and rim factory. (It means most value for first cost, as well as the ultimate economy of Most Miles per Dollar.)

Firestone
TRUCK TIRES

on Firestone Quick Removable Rims permit rapid and easy tire change by anybody, anywhere *without special tools*. And the Firestone Shops in all truck-using centers form an unbroken chain of service to keep your trucks in commission.

Road Structure and the Commercial Car

(Concluded from page [illegible])

in a solid mass, curving out from the curb at each side, those nearest the curb being held by the greater friction in almost their original position, those at the center being the keystones of an arch that has its apex pointing in the direction in which the traffic is traveling. Seams are thus opened up at the beginning of the stretch of roadway affected, causing bad bumps to heavy vehicles passing over them, and at the end of the stretch, blocks are often forced completely out of place. This curious glacial movement should, as has been said, have particular interest for the truck maker and user, since it is directly due to heavy motor traffic, and reacts directly upon that traffic in a deleterious manner. The matter of foundations for road structures should receive the most careful attention from those interested in the welfare of the commercial motor vehicle, for while the surfacing is most in evidence, and while it does the actual carrying of the load and must be depended upon for taking the brunt of the work, it can only do its share and no more.

Let us consider for a moment railroad work. Here the quality, weight and strength, as well as a number of subordinate but co-ordinate factors, of the steel rails, ballast, spikes, ties, plates—all that go to make up the railroad roadway, are known. The various parts are selected for their individual and collective efficiency, and these efficiencies, governing the safety, speed, and tonnage of trains and engines, are known, not only to the line's operating department, but to the builders of the coaches, gondola cars, Pullman diners, locomotives—in fact, to all those who manufacture rolling stock of any nature for the railroad's equipment. It may be said, and quite truly, that the railroad company not only runs the trains, but is also responsible for the roadbed; that is one reason why the railroads are able to provide the wonderful service that they do. Does it not seem as though it were up to the motor-truck manufacturers to take a hand in the building and maintenance of the roads and streets—the "rails" over which their "rolling stock" has to travel and demonstrate its worth to the commercial world?

Motor Truck Notes and Queries

L. L. S. writes: "There is an annoying squeak that seems to come from the springs of my one-ton truck. The machine has recently been overhauled, but it may be that the springs were not properly lubricated. What oil should be used, and how should it be applied?"

A. The frame of the car should be jacked up so that the axle is suspended from the springs. This will tend to separate the leaves of the springs somewhat, and then a mixture of thick oil and graphite or a graphite grease may be introduced between the adjoining surfaces of the leaves by means of a thin-bladed knife. Special devices are on the market, by means of which the leaves may be separated by tightening a nut that serves to introduce a wedge-shaped point between adjoining leaves. Although a portion of the truck that is too often neglected, yet it is the springs that are subjected to almost continuous work when the machine is in motion.

T. P. P. writes: "I have 4½-inch pneumatic tires on my delivery car, and desire to keep them pumped up to the pressure recommended by the manufacturers. What are the so-called 'spark plug tire pumps,' and are they injurious to the tire?"

A. The pumps to which you refer consist of a double cylinder, one end of which is designed to be screwed into the spark plug opening of one of the cylinders. When the engine is run on the remaining cylinders, the compression in the "dead" cylinder operates the plunger of the cylindrical pump, and *fresh* air is pumped into any tire with which the long tube extending from the pump may be connected.

If a gauge is used to determine the correct pressure, you will find that these gauges give excellent results at a great saving in time and labor. Inasmuch as the pure outside air is pumped, the objection that the uninformed hold against them—to the effect that the gasoline in the mixture as it comes from the cylinder and is pumped into the tires, tends to rot the fabric—is seen not to be valid.

Basket Willow Culture in the United States

(Concluded from page 439.)

according to the soil. In moderately moist, porous soil they should be from 8 to 10 inches, but where the water level is below 6 feet they should be 12 inches long. To plant them too close together or too far apart reduces the commercial value of the crop. From 9 to 12 inches apart in the row and 2½ feet between the rows is the usual spacing followed. If planted far apart they produce thick tapering rods, which are less valuable.

Harvesting the rods begins about the middle of January, and this work must be completed before the sap commences to rise. The young shoots are cut with a short hooked knife as close to the stump as possible. The rods are next tied into bundles and placed in a pit of running water from 4 to 6 inches deep. They are left in the pit until the sap rises, when the bark is easily removed. This is known as sap peeling. Another method, known as steam peeling, consists in steaming or boiling the rods until the bark loosens, when it may be removed by hand. The apparatus for peeling consists of a round steel rod from ½ to ⅝ of an inch in diameter and about 4 feet long, which is doubled over so that the two ends are brought together, making a double rod 2 feet long. The lower or welded end of the parallel rods must be inserted vertically in a log placed at a convenient height. The operator places the thick end of the rod between the prongs and draws it toward him, and the bark is separated from the wood. The small end is then treated in a similar way, which completes the operation. The next operation is grading the rods into proper height and quality classes, after which they are bundled up and prepared for market. The market price for green unpeeled rods, cut and delivered at the railroad, ranges from $10 to $30 per ton. From 4 to 8, or sometimes 10 tons, may be grown on an acre. The crop from an average acre should bring $150, of which one half should be net profit.

In Pennsylvania and Maryland the willow growers prefer to cultivate the American green willow, which produces longer and stouter rods. The methods of culture and of handling the product after harvesting are practically the same as in New York, and it will be unnecessary to enter into details, but simply note one or two points in what may be called the Pennsylvania-German system. Here cuttings are planted in rows of from 18 to 24 inches apart and from 8 to 10 inches apart in the rows. This method of spacing renders the stand very dense. In this region willows are considered wet-soil demanding plants, and nearly all plantations occur along streams. In New York the best land on the farm is appropriated for growing willows, because this crop in rich soil and under intensive management yields a return equal to or greater than most other farm crops. While these plantations produce rods of the highest quality, it must be admitted that many plantations in Pennsylvania and Maryland produce a quality of rods that cannot be surpassed in any part of the country or even abroad, where willow culture has been practiced for over 800 years.

The Principle of the Bicycle Applied to the Motor Car

(Concluded from page 443.)

the car is on an even keel the rack R and the pinion U are not in engagement, but a very small upward movement of the rack is sufficient to establish such engagement.

It will thus be seen that if the car swings over to the right the left-hand rack R and pinion U are brought into mesh. If the swing

Heavy Duty G. V. Electric Trucks

This is one of the G. V. Electric trucks used by the Bethlehem Steel Company. The daily mileage is small but the truck solves the problem of yard transfers at minimum cost.

One of the several 5-ton trucks used by the National Sugar Refining Company made 10,989 miles in 300.5 working days in 1913. This was an average of 33.24 miles per day, while the rated mileage of the truck per battery charge is but 35 miles. This mileage was made, too, on short runs from refinery to railroad and warehouse.

A 5-ton G. V. Truck in Wisconsin moves both flour and grain in one non-dumping body, the wheels being clamped to a platform which tips sufficiently to discharge the grain. The round trip is but 1,700 feet and the truck is charged but twice each week. Yet it displaces 6 horses and 3 men.

We have about 4,000 G. V. Trucks in service. Some make 60 miles per day and some but 12 or 14 miles, the latter in mill yard work.

Write us about your short haul problem or for bulletin No. 101.

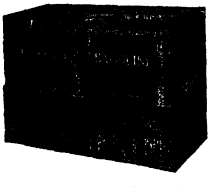
HAVOLINE OIL
"It Makes a Difference"

in Efficiency, Expense and Endurance *in your car* because:



The Base—It is made only from one uniform base, crude oil of tested quality and sameness.

The Process—It is manufactured in a manner which leaves the *molecules of the oil entirely whole*, thereby preserving its life and increasing its lubricating value. It is entirely freed from floating carbon and impurities.

Result—A uniform oil, that forms an even lubricating "cushion" around the metal surfaces and prevents wear and tear upon them, retains its vitality yet is free from foreign substances. Leaves minimum carbon deposits. Reduces repair bills. Prolongs life of motor and increases its efficiency.

Buy the oil in the Blue Can. *2 Five Gal. Cans to the Case.*
Tell us your make and we'll tell you your grade. *If your dealer cannot supply you, get it from us direct.*

Ask your garageman or write us direct for testimonials of Havoline users, owning your make of car.

THE JOSEPH DIXON CRUCIBLE CO.
JERSEY CITY, N. J.
Established in 1827

is to the left the right-hand rack and pinion are engaged.

We now come to the gyroscope and its details. The gyroscope wheel *A* (Fig. 3) is mounted inside a cage consisting of top and bottom plates *B B*, four corner pillars, and two cross bars *C* These cross bars are provided with pivots *D*, which pivots are carried in bearings on the pillar *P* (Fig. 2) directly behind the pin joint *Q*. Returning to Fig 3, it will be noticed that the plane of rotation of the gyro-wheel is above the line through the pivots *D*. In this respect Mr. Schilowsky claims that his system is different from the gyroscopic monorail carriages of other inventors The difference seems little enough, but it has a very marked effect on the behavior of the device It would, however, lead us, were we to discuss this point fully, into a long and tedious mathematical analysis of gyroscopic phenomena in general Suffice it to say, then, that the gyroscope spindle *E* is directly connected to an electric motor carried on the lower plate *B* (Fig 3) and indicated by the dotted lines *F* The speed of rotation of the gyro-wheel is 3,000 to 4,000 revolutions per minute.

The upper end of the gyro-spindle carries a worm *G* which meshes with a worm wheel *H* carried on a shaft *J* This shaft is journaled in bearings on the top plate *B* and is disposed crosswise of the car that is to say, at right angles to the track. At one end the shaft *J* carries a gear *K*, which, meshing with a second gear *L*, transmits motion to a second and parallel shaft *M*. At the other ends of the shafts *J* and *M* are pinions *U*, which pinions are those similarly referred to in Fig 2 It is clear that if the gyro-wheel is rotating anti-clockwise when viewed from above, the direction of rotation of the gears will be as shown by the arrows Viewed as drawn in Fig 3, the left hand wheel *U* has a clockwise rotation and the right hand one an anti clockwise

Imagine, once again, that the car is lurching over to the right. As all acquainted even but slightly with the properties of the gyroscope are aware, such a movement as this—or, to be quite exact, the application of the torque implied by this movement—will cause the gyroscope to precess round an axis at right angles to the axis about which the movement is taking place This last axis is, of course, the line of motion of the car, and the axis about which precession is set up is that of the pivots *D* (Fig 3) With a right hand lurch the upper end of the gyro-spindle *E* goes forward, so that the pinion *U* on the left-hand side moves into some such position as *W* (Fig 2)

So long as a lurching over to the right continues so long will the gyroscope, if left to itself, continue to precess But it is not left to itself As we have said above, a right hand lurch causes the left-hand rack *R* (Fig. 2) to rise, and the lurch has not proceeded very far before the rack and the rotating pinion *U* come into mesh As soon as this occurs the precession is checked, for the pinion *U*, rotating in the direction of the arrow *X*, obviously will pull the rack round on its pivot *Q* in the direction of the arrow *Y* Under these circumstances, then, the precession is checked by the force of the spring *Z*

Now, when the gyroscope is mounted as is this one, and when its precession is checked, it develops a torque about an axis—the line of motion of the car—at right angles to the axis of precession Why it should do so cannot be explained without a considerable amount of analysis But we may say that the same fundamental principle is at work here as in the case of an ordinary spinning top It is a matter of common observation that if we hasten the precession of a top it will lift its axis more nearly vertical If we check or retard the precession the axis tends to fall

In the case of the gyroscope in the Schilowsky bicycle automobile the torque developed by the checking of the precession opposes the lurching, so that the overturning couple is overcome The restoring couple developed by the gyroscope continues in action until the car has so far righted itself that the rack is lowered by the pendulum out of engagement with the pinion *U* In actual running it requires very close watching to discover that the gyroscope is continually processing in one direction or the other But it can be seen and at the same time it will be noticed that the racks *R* are continually rising, checking the precession, and falling again

The inventor claims that a mono-track motor car, running under gyroscopic control, may attain a given speed and efficiency with a much less powerful engine and with a lighter frame and body-work than would be required for a four-wheeled car of the same rating. He also points out that a mono-track car requires only the narrowest of paths, hence its special applicability for use in new and undeveloped countries Further advantages are said to be a gain in smoothness of running, a lessened fuel consumption and cost of production, and a gain in safety when running at high speed on horizontal curves

The weight of the gyroscope is one tenth to one twenty-fifth of the weight of the fully loaded car and the expense of energy for running the gyro is 1.25 brake horse-power at a maximum.

More than all other High Grade American cars combined, selling at or more than the Cadillac price

Such is the record to date of this year's Cadillac sales

More than half of the buyers of high grade cars, investing $1975 or more, have this year shown their preference for the Cadillac.

More than half of such buyers, after carefully weighing the evidence, have decreed the Cadillac to be the car which offers the greatest value in the investment.

More than half of such buyers, after mature deliberation, have reached the conclusion that the Cadillac is the car which evidences the greatest advancement in motor car development.

More than half of such buyers have adjudged the Cadillac to be the car which provides the highest degree of comfort, luxury and convenience.

More than half of such buyers have awarded the verdict to the Cadillac as the car which affords the acme of all 'round efficiency.

More than half of such buyers believed the Cadillac to be the car which contributes most to lasting satisfaction and contentment.

More than half of such buyers were convinced that the Cadillac is the car which provides, in most abundant measure, all of those qualities which contribute to the charm of motoring.

Has ever a motor car received such overwhelming endorsement?

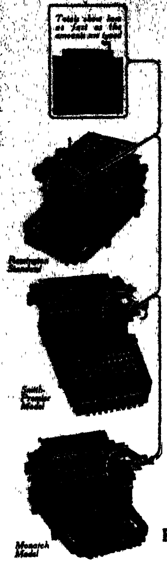
Cadillac Motor Car Co. Detroit, Mich.

Don't say, "Oh, this announcement is for my bookkeeper."

It is for you

It shows how you can save hours of clerical time



Without this all-around machine, your billing clerk goes through three time-consuming acts:

Act 1.—Writing the bill.

Act 2.—Footing.

Act 3.—Proving the total.

This complete correspondence typewriter does all three simultaneously. With cold steel accuracy, it automatically foots and proves your bills *while it types them.*

It soon pays for itself in this saving of clerical time alone—to say nothing of the errors prevented.

You owe yourself an *early* investigation.

Your first doubt will be: "Can I be sure that this machine is accurate?"

That is answered by the United States Sub-Treasury and prominent banks throughout the country, who use it constantly.

Your next, "Can I apply it to my present billing system?"

That is answered by thousands of business offices and retail stores—large and small—who are using it without the slightest change in system.

It does your work *your* way.

A new illustrated folder—"The Story of a Day's Work" describes the workings of this remarkable time and money saving machine. Briefly and interestingly, it points out the uses for the Remington Adding and Subtracting Typewriter—in your own store or office—on your own bills and statements "The Story of a Day's Work" carries a really worth-while message for any employer of clerical or stenographic help—regardless of the size of his business You would hardly want to miss it—so while you think of it—send for your copy—TODAY

How it saves time

Take a simple case. Suppose you are typing a bill and your first item is 50 lbs. coffee @ .31—amount $15.50. When you come to the amount press 15.50

The figures are typed on the bill head.

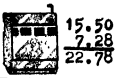
Now look in the totalizer! Right in front of you it flashes 0 000 015 50

Now for your next item. Call it a barrel of flour @ $7.28. Type 7.28

The totalizer immediately shows the total of the two amounts—0 000 022 78

The total is always there as soon as the figures are typed.

Now touch the subtracting lever and enter the footing shown in the totalizer. Press 22 78



Your correct total is typed before you. Your totalizer now shows 0 000 000 00

That row of cyphers *proves* that the total has been correctly entered. Not a moment has been wasted Send today for "The Story of a Day's Work."

SAXON $395

The Gasoline Toll Gate Does Not Stop You in a Saxon

Saxon owners are saved the annoyance and expense of frequent stops to pay toll at the gasoline stations. The occupants of the light but sturdy Saxon drive by in comfort while many a touring party in a big, heavy car is held up for fuel replenishment.

Thousands of owners daily find the Saxon the most economical car they ever drove; they consider it the most economical car of standard design in the world—to buy and to run.

A Year's Service in a Month

And the Saxon saves you money every day you drive it. Here are some economy records from a test made in Detroit, representing the equivalent of a year's service. Note them carefully:

[illegible] miles a day for [illegible] days.
[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
[illegible]

Similar records of gasoline and tire economy are reported to us by owners and dealers all over the country No wonder Saxon owners say: "It's cheaper to drive a Saxon than to use street cars—especially when you consider the time saved."

Not only does the Saxon give pleasure and health at moderate expense—to those who don't want to pay an extravagant price for a car; to those who already own a big car; to those who need a car for summer vacation use. ITS WONDERFUL ECONOMY IS A REASON ALSO FOR USING IT IN BUSINESS.

Order Your Saxon Now

Saxons are selling fast—faster than we ever dreamed they would. It must be a case of first come, first served. So the only way to avoid being one of the disappointed is to see your dealer and order now.

Catalog and dealer's name on request.

FOLMER & SCHWING DIVISION
EASTMAN KODAK CO.
ROCHESTER, N. Y.

An automobile should weigh less than 3000 pounds

WHEN we say "Automobile" we mean the average type of car, the five-passenger touring car of 120-inch wheel base. That is the correct length of car for comfort. Less length is not enough. More is unnecessary.

Up to a year and a half ago all cars of this size—both four-cylinder and six-cylinder—weighed from four to five thousand pounds. Most of them still do. That's *two to two and one-half tons.*

Is such weight *reasonable?* Is it *necessary* for *safety* and *durability* and *comfort?* Some manufacturers would ask you to *think so,* but can you imagine it? Three or four years ago it *was* necessary,—not for safety or durability or comfort, but simply because no manufacturer *knew how* to build *lighter* cars and *build in* the required qualities.

The world moves. *Some* of the *people* stand still for a time, but the *world* goes on. And with the rapid development of automobiles came a parallel *demand* for *lighter weight,* just as came the demand for six-cylinder *continuous, smooth* flow of power.

The public said: "We *want* cars. We know the pleasure of the automobile. We know its utility. But we are staggered by the expense. Tires wear out so fast and they cost so much! The motor eats up so much gasoline and it costs so much! Why can't *lighter* automobiles be built, with *just* as much safety, just as much durability, just as much comfort? Why not?"

Well, *why not?* A couple of years ago *some manufacturers* began to think seriously on that question. Among them were the men who built the first Chandler Light-Weight Six a year-and-a half ago,—men who had been designing and building and selling the highest grade motor car in America for years. And for years before that, the finest bicycles.

We certainly knew motor car construction, we knew six-cylinder construction, we knew automobile engineering, we knew that the demand for light weight was logical, and we felt sure we could build a six-cylinder car of 120-inch wheel base that would possess every known degree of safety, of durability and of comfort and *not weigh more than 3000 pounds.*

How, you may ask, did we hope to cut off that fifteen hundred or two thousand pounds!

Someone suggests that light weight comes from cheap materials. Not at all. *Cheap iron* is just as heavy as *good* iron.

We were going to *cut out the iron.*

And we cut it out.

It's the people who haven't cut out the iron that are "warning" you against light weight.

We cut out the heavy castings that add weight but *not* strength to a car. And what did we use in their stead? *Aluminum,* and *pressed steel.*

Are they as strong? Ask any engineer you chance to know.

It takes two men to lift a *cast iron* crank-case. But you can put an *aluminum* crank-case under your arm and walk away with it.

Which would you rather have, the cast iron or the aluminum?

Another factor in the Chandler light weight is the use of high-grade, efficient, imported ball bearings throughout in place of the heavy friction-producing roller bearings with their heavy cases and carriers.

And so on, all through the Chandler, we cut out *weight* without sacrificing one single degree of strength.

Is it *durable?* Ask any Chandler owner. We will refer you to as many as you want, and in any part of the country you say. *Of course* the car is durable. We started with a *clean slate,*—no errors to forget, no faults to overcome, and we built it so that it *had to* endure.

Is it *safe?* A year's service has brought no report of a *break-down.* Hundreds of owners have done five to ten thousand miles without a single repair. In the Swedish Reliability Test, conducted by the Swedish Royal Automobile Society in February—over 800 miles of storm-wrecked roads that experts declared impassable—the Chandler was the only American-built entrant with no failure to finish. In all other endurance tests it has finished with honors. Do not these qualities spell safety? The Chandler gives you *100 per cent safety.*

Is it *comfortable?* We will let you answer that for yourself. The car will tell you all about comfort better than we can. Go to your Chandler dealer—there's one in every principal city in America and in hundreds of smaller cities. Go to him and say, "Prove to me that a car weighing less than 3000 pounds is as comfortable as the heavy cars. Let me pick out the roads. Drive me where I want to go. Get away from the boulevards. Take me fifty miles out through the country and *drive fast.* Hit all the bumps. Let's see if it's comfortable."

Put it up to the Chandler man just like that. Don't worry about hurting his feelings. He's *waiting* for you.

Heavy Car Builders Do Not Name Weight

You have noticed, of course, that practically all manufacturers are *talking* now about lighter weight. But it's mostly just talk. Read the advertisements, "A light car and a speedy one," "How much should an automobile weigh," "The unmistakable demand for light weight," "Our car is 300 pounds lighter," "Our light six is just the right weight," and so on and so on. A lot of fine sounding talk, but NO FIGURES. If they are proud of 3700 lb. weight or 4000 lbs., or 4500 lbs., why don't they *name* the weight! And have you noticed that the *only* cars whose weights are *advertised,* weigh less than *3000 lbs.?* All the others will name their weights, too, when they reach the 3000 lb. mark, *but not before.*

CHANDLER $1785

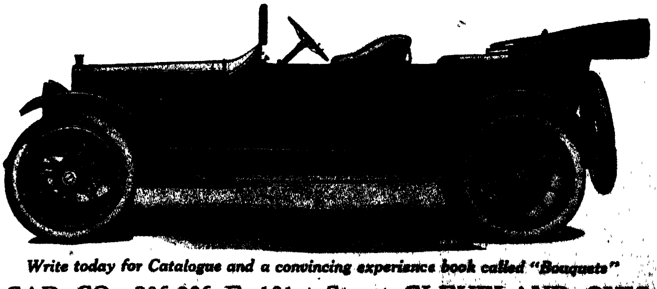
LIGHT WEIGHT SIX

Weighs 2885 pounds fully equipped
Runs 16 miles per gallon of gasoline
Averages 7000 miles per set of tires
Speed, 3 to 55 miles per hour on high gear

Remember the Bicycle!

YOU probably recall the 60-lb. bicycles. *Everybody* made them heavy, and a "century run" was an *event.* Then a pioneer who was *thinking* cut off 28 lbs. in one stroke. Built bicycles that weighed 32 lbs. Other manufacturers *warned* the public. Said light weight bikes couldn't *stand up,* and would "jolt the rider all to pieces." Within two years *all bicycles* were *light weight, lower priced,* stronger, more durable, just as *smooth-riding* as ever, and century runs were *commonplace* because of the *economy in power.*

History is repeating itself.



Write today for Catalogue and a convincing experience book called "Bouquets"

Threatening to engulf a cottage.

The ice piled itself up in huge billows.

An Ice Flood

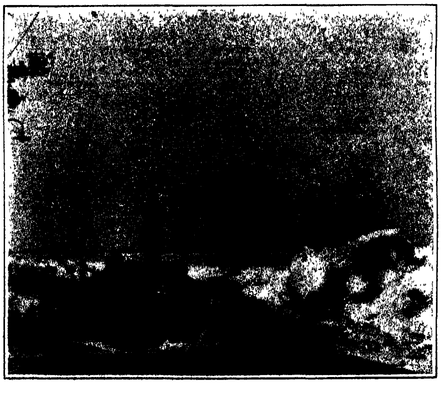
By W. F. Anderson

ON the afternoon of Easter Sunday there occurred at Sylvan Beach, N. Y., on the shore of Oneida Lake, a very sudden transfiguration of the scenery, as will be observed from the photographs shown. A field of ice came up out of the lake like a tidal wave and piled itself in huge billows upon the shore.

The ice on the lake averaged about 12 inches in thickness and was melted along the shore for a distance, on the average, of about a hundred feet out. At this particular time a severe gale began blowing and moved the ice shoreward with such force, that, from the momentum gained, it was forced out upon the beach and over the concrete sea-wall. In some places the sea-wall was entirely wrecked. The ice continued to pile up till, within a period of twenty minutes, it had reached a height of thirty feet in places, and reached along the entire length of the southeast shore of the lake.

One picture shows the ice piled on top of the roof of the front porch of a cottage. This cottage was practically demolished and the whole interior was filled with ice. There was no way of combating this glacial flow.

Old inhabitants of this vicinity claim that a phenomenon such as this has not been seen here for over twenty-five years.



In some places the concrete sea-wall was wrecked.

The ice billows reached a height of thirty feet.

How It Feels to Travel by Flying Boat

AN admirer of, and occasional contributor to the SCIENTIFIC AMERICAN, recently made a flight as passenger in a Thomas flying boat, which has been located at Dobbs Ferry, on the Hudson River, for the past few weeks, doing "missionary work" in the cause of aviation. A first flight is always interesting, and an invitation from the manager, F. Rodriguez, to make such a flight with Ralph M. Brown, was quickly accepted. Upon the advice of the preceding passenger, the writer stuffed cotton in his ears first. Slipping on the airman's padded jacket, he stepped aboard the boat at the bow just after Brown had beached her and opened the hinged doors forming the deck of the bow, by pulling a lever. He found a comfortable seat beside the aviator, with plenty of room to stretch his legs. The big 6-cylinder Austro-Daimler up above, between the planes, was running slowly. Two men in hip-boots pushed off the boat and swung it around until it could be steered out into the river. The big engine stopped sputtering and emitted a steady roar. Instantly the boat scooted over the water diagonally across the Hudson. It tore along at 60-mile speed until it "bumped the bumps" on the waves of a passing steamboat. Then perfectly smooth motion and no more spray drew one's attention to the fact that it had left the water and was ascending along a gradual incline. The waves soon appeared to be ripples, and the steamboat a toy craft, as the aeroplane circled around her at a height of 500 feet Brown let the machine tip naturally, and the angle it assumed was such as to make one feel uncomfortable and fearful of side slipping, although the inclination was scarcely any more, perhaps, than a train tips when rounding an extremely sharp curve

Once on the straightway up the river, one had a chance to glance to one side or the other and view the beautiful grounds of the country places, appearing like models of landscape gardens, one tenth of a mile below.

At the 70 miles an hour at which we were flying the wind pressure was so strong, however, that if one turned one's head ever so slightly the pressure on the foremost ear was decidedly uncomfortable Even with cotton in the ears, the roar of the air by them was almost sufficient to drown the exhaust of the motor Tears formed in the eyes, but were quickly blown aside. When provided with goggles and a skull cap, flying at high speed must be delightful and exhilarating An automatic stabilizer will eliminate steep tipping at the turns and a celluloid windshield the strong air pressure. Flying above water at a low elevation is quite as safe as motoring and much more pleasurable, and the reason for the popularity of the flying-boat ferries that have been started in the South and West is easily seen. For the business man who commutes a distance of 50 to 75 miles, a flying boat will *more than pay for itself* in health and pleasure derived in a single season.

A Remarkable Collection of Human Embryos is being made at Johns Hopkins University under the direction of Prof Franklin P Mall, whose private collection constituted the nucleus of the new one. Circulars distributed to physicians throughout the United States and abroad have resulted in the addition of about 150 specimens within six months, many of them unique. Special care has been taken to secure accurate histories of this material. Series of specimens from the collection are lent for study to persons engaged in working out special problems in embryology, and important investigations are also being carried on by Prof. Mall and his assistants.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest If the photographs are *sharp*, the articles *short*, and the *facts authentic*, the contributions will receive special attention Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Lost Through Insufficient Subdivision

THE loss of the "Titanic" with 1,500 souls was due, as we showed at the time, to insufficient subdivision. The rupture of the outer skin permitted the water to fill the ship from side to side, in the compartments affected. An inner skin, laid upon the frames, or in the form of the inner wall of coal bunkers built along the sides of the ship, would have kept her afloat long enough for all the passengers to be saved by rescuing ships.

Since that disaster, the "Olympic," sister to the "Titanic," has been made a safe ship, by the construction of an inner watertight skin some three feet in from the outer shell of the ship

The ill-fated "Empress of Ireland," which was sunk in the St Lawrence, on the 29th of May, with the loss of nearly one thousand souls, as the result of being rammed by a collier, was built under the same faulty Board of Trade rules under which the "Titanic" was built She was provided with nine transverse bulkheads; but she possessed no side longitudinal bulkheads, nor had she any inner skin. When she was pierced by the bow of the collier, the water was free to fill the 65½ foot width of the compartments affected. The inrush of water was so rapid that the ship began at once to list heavily, and *in fourteen minutes this 20,000-ton ship had capsized and gone to the bottom!*

It so happens that we publish, in this issue, the plans of a ship, the "Aquitania," which makes her maiden voyage to New York this week, whose construction, with side bunkers, is such that she could have sustained the blow of the collier "Storstad" without being sunk, and indeed without any serious risk of being sunk The moment the stem of the collier touched the side of the "Empress of Ireland," it was twisted aside, and the bow was so greatly blunted that it would never (had the ship been the "Aquitania") have crushed through the eighteen feet of coal in the bunkers and reached the inner skin

In the presence of this ghastly repetition of the "Titanic" disaster let us keep our eyes on the big facts These hapless people (nigh a thousand of them) were drowned because the ship was not built *unsinkable—and it is perfectly possible to build ships so well subdivided* that they cannot be sunk—certainly not in fourteen minutes—by collision. The "Empress of Ireland," like the "Titanic," was a safe ship, judged by the British Board of Trade requirements as to safety. But *at the time of her construction the safety requirements* of the British Board of Trade were ridiculously inadequate. They allowed a ship to fill two adjoining compartments and bring the top of her bulkheads to within a foot or two of the water and pronounced her *safe when in that condition.* Whether the "Empress of Ireland" filled more than two compartments we do not know at the present writing; but we do know that it took just fourteen minutes to send her to the bottom.

The big thing to remember in the investigation of this disaster is that the one sure protection for a ship against sinking is an inner skin—the ship within a ship The naval constructors have adopted this protection for battleships against the ram and torpedo, and they ought to know.

It is a matter for deep regret that the great International Conference which sat for several months, last winter, in London, did not make the provision of an inner skin obligatory They left it to the judgment of the individual companies and their naval architects

The findings of this Conference await ratification by our Senate. We strongly urge that, in view of the recent disaster, our Government should incorporate a clause making some form of inner skin obligatory on all ships carrying more than a certain number of passengers.

The Regulation of Harbor Traffic

THE growth of population, with its corresponding increase in the density of traffic in our large cities, has led to the organization of "traffic squads," whose sole duty it is so to regulate the movement of vehicles through the streets, particularly at congested points, that it shall proceed with the least possible interruption and in the greatest possible volume Residents of our largest cities will remember how the unregulated traffic would frequently become so completely tangled up as to come to an absolute standstill, and require many minutes to loosen out the congestion and set the mass of vehicles in motion again.

We borrowed the idea of a specially organised street traffic police force from abroad, and it has worked so well in this city, that such a thing as an absolute deadlock in traffic, even at the most congested centers, is now practically unknown.

When we come to consider the question of river and harbor traffic, we find that like causes have produced like results. Of course, there is at present nothing comparable to the confusion and absolute deadlock that formerly occurred on our city streets; nevertheless there is a feeling among shipping men that the time has come for introducing some form of authoritative regulation of the movements of shipping, in order to prevent delay, avoid accidents, and get the maximum traffic efficiency out of the more crowded waterways of our leading ports and harbors.

Not many weeks ago, we had occasion, in these columns, to comment upon a serious accident to one of our ferryboats in the North River, which, as we pointed out, was due to lack of stringent laws protecting the navigation of these boats. The trouble, however, does not come from them; for, as a rule, our ferryboats are superbly handled. Indeed, when we remember that their courses lie largely across the track of shipping in one of the busiest ports in the world, it must be admitted that the work of the ferryboat captains is well done.

The chief obstruction and delay comes from the lighters and other slow-moving traffic. During the period of heavy ebb and flow of the tide, the current is so strong that the handling of heavy loads is extremely difficult, and often the tows are brought practically to a standstill, in which case they become a most serious impediment in the handling of large ships in the river. A notable instance of this occurred in the recent docking of the "Imperator," which, after she was straightened out across a rather strong ebb tide, and was about to enter her dock, found the entrance completely blocked by a tug which was vainly endeavoring to push its heavy tow upstream against the current. The big ship had to drop downstream, with the result that it was some hours before she was finally moored in her berth. Such incidents are liable to occur at any time when the large modern liners are making their piers. There is a feeling among shipping men that the time has come for the appointment at this port of a Harbor Master, who, with his staff, shall serve the purpose of a traffic squad in the North and East Rivers. The large ports of Europe are controlled in this way, and experience has proved that thereby the speedy and safe handling of shipping is greatly facilitated.

Problem of the Permanent Road

FOR many years the management and the engineering staff of our railroads have well understood that the provision of an absolutely first-class roadbed and track, in respect alike of its construction, grades and curvature, was most intimately related to the question of profitable operation, and it is with a clear recognition of this fact that our larger railroad systems have expended during the past two decades hundreds of millions of dollars in cutting out curvature, reducing grades, strengthening bridges, and increasing the weight of rails and fastenings

There is to-day a growing appreciation of the fact that the same economic conditions apply to the construction and maintenance of the country's highways. Here the matter of grades is not of such vital importance; but the importance of providing a solid and well-founded roadbed, properly drained, and provided with a top surface of such a durable character that it will preserve a true and solid surface for a long period of years, is receiving the fullest recognition. It is coming to be understood that the question of first cost has been given undue importance; we now know that the extra initial expense of an absolutely first-class and durable road, that is subject to heavy traffic, is more than compensated by the elimination of costly repairs, and of the great loss (an item which has received too little consideration in the past) due to the long periods of time during which the road is out of service because of repairs.

A few weeks ago, we had occasion to refer to a report of Governor Glynn of this State, in which he showed that there would be an enormous saving of cost over the present macadam roads, with their limited life and their exceedingly costly repair bills, if they were built with a brick surface upon a well-constructed foundation. In this report the Governor states that in New York a mile of macadam costing $12,000 does not last over ten years, and that its maintenance would cost about $1,000 a year, with the result that at the end of ten years the road must be rebuilt at a cost for reconstruction of $6,000 a mile. The total expenditure for twenty years on a mile of macadam road therefore amounts to $36,000, including $12,000 for building, $18,000 for maintenance, and $6,000 for rebuilding at the end of the first ten years. As against this the report pointed out that the total expenditure for twenty years on a vitrified brick road would amount to $26,000 *only*, estimated at a maximum of $25,000 for building and a maximum figure of $50 a year for maintenance.

We find a verification of this report in an address given by Mr. Will P. Blair, at the first Canadian and International Good Roads Congress at Montreal held last May, the subject of the address being the economy of a vitrified brick road. The author lays stress upon the fact that the greatest element in fixing the economy of any road is the very one which is least taken into account; namely, its out-of-repair condition. On many types of road, break-down of the surface is so frequent as to call for almost complete reconstruction; and at such times a stretch of road may be put entirely out of commission. The sum of the periods of times that the road is out of actual service, coupled with the smaller loads that can be hauled over an inferior road, the broken springs, the extra wear and tear of the vehicles, etc., if converted into dollars, might equal, in a surprisingly short period of time, the entire original cost of the improvement.

The author of the paper gives some useful facts as to the experience already had with brick roads in this country. It seems that the main streets of Belleville, East St. Louis, Alton, and Danville in Illinois; of Terre Haute, Richmond, Frankford, and Lebanon in Indiana; and of Portsmouth, Chillicothe, Sandusky, and Conneaut, Ohio, are brick paved. All of these streets, he stated, have more than an average life of twenty years. In Cleveland and other large cities, many streets have brick pavements whose average life exceeds twelve years. Moreover, there are hundreds of streets paved with brick to be found throughout the above-mentioned towns which have been in use over ten years, all of which have not called for a penny of repair work due to wear and tear. The significance of these facts will be evident when it is borne in mind that the average traffic upon these streets is at least twice that of any traffic that is borne upon any part of the country highways of the main market or interurban systems.

Form and Substance

CHANGE is the order of Nature. Yet, in the ever-shifting landscape of the world's events, we have learnt to distinguish two stable landmarks, *Matter* and *Energy*. The recognition of this constancy represents, to the physicist, one of the great central truths of science. But from a more "human" point of view, there is something unsatisfying about this permanence of substance. For what counts, in life, is not the substance, but the form. And the form is fleeting, though the substance abide. What if the changing seasons leave the total mass and energy of the universe unaltered? Spring brings its buds and blossoms, Summer ripens, Autumn gathers in the fruit. These are the things that matter. What comfort, when the living form is fled, that the total substance be unaltered? Life is one ceaseless endeavor to preserve a form, an effort in which sooner or later all are vanquished.

Yet, for a time the organism does succeed in preserving that characteristic form on which its life, its consciousness depend. And, strangely enough, here, in a sense, conditions seem reversed: while the form is constant, the substance is forever changing. The human body, for example, might be likened to a house, the bricks of which were continually being removed and replaced by others, in such way that the form of the building be carefully preserved. The life of man, his very identity, depend, not on the bricks of which he is built (for they are replaced from day to day), but on the form in which his structure is raised. And this constancy of form, which for a time is his, unlike the constancy of mass, is not inherent in the nature of things, but must be purchased by continued effort. And sooner or later the effort fails, and that form which means all to the organism crumbles and decays.

As if by an irony of fate, while Nature has guaranteed the permanence of substance, at any rate for eons to come, the very things by which we set most store depend on form, fleeting, evanescent.

Electricity

Buying Current for Electric Railways.—At a recent meeting of the Illinois Electric Railway Association in Chicago, Mr. Peter Junkersfeld gave an address on power production for electric railways, in which he brought out the fact that while in 1902 electric railways purchased very little power, ten years later 33 per cent of all the power used was purchased. Illinois, in 1912, purchased electricity amounting to 58 per cent, while in Chicago, during the first few months of the present year, surface and elevated railways used 90 per cent of purchased electrical energy. This shows that electric service companies, by producing in large quantities and specializing, are able to furnish electricity cheaper than the railways can manufacture it for themselves.

New Lights for Turin.—The city of Turin is occupied with the task of reorganizing the public lighting on a modern basis, and no less than $400,000 will be employed for this purpose, the work to be carried out from 1914 to 1916. According to the plans, arc lamps will be used in all the main streets and avenues, also the public squares, while smaller streets are to be lighted by incandescent lamps. Flaming arcs in closed globes will be used. About 3,000 lamps of 2,000 candle-power each will be installed. In some places, incandescent lamps are used, some being of the 500 candle-power type, and the rest of 100 or 200 candle-power. These are much better than the present gas lamps, which give only 50 candle-power. Current for the whole system comes from the municipal electric station.

Hydro-Electric Plant for Washington.—A bill has been introduced in the Senate providing for the development of electric power from the Potomac River at Washington. According to the plan, the Potomac River is to be dammed at the Chain Bridge, just above Washington. The dam is to be 115 feet high, and would make a lake 9 miles long, extending as far as Great Falls, where the city now obtains its water supply. The plant would develop 99,000 horse-power. The Government now uses a steam plant producing 10,000 horse-power, and about 1,000 horse-power more is bought from an electric power company. With its own power plant, the Government could obtain all the electricity it needed at a much lower cost, and would have, in addition, plenty of current to sell at a low rate to railways and factories.

First Prosecution for Violation of Wireless Laws.—A wireless amateur of Los Angeles was reported to the United States Attorney for operating his station without a license, and causing interference, being a violation of Section 1 of the Act of August 13th, 1912, to regulate radio communication, for which a penalty of $500 is provided and the apparatus may be confiscated, in the discretion of the court. Judge Wellborn, of Los Angeles, in passing sentence upon the offender, stated that as this was the first prosecution under the law in his district, he would assess only a nominal fine, with the understanding that all future prosecutions under this Act would be dealt with summarily, and the punishment materially increased. In view of the fact that the offender had disposed of his radio apparatus shortly before his indictment, the judgment did not include the confiscation provided by law.

Look Out for the Wires!—The New Haven Railroad has issued a warning to all persons along the line of its present electrical extension, notifying them, and particularly the small boy, that the wires are soon to be charged. As a voltage of 11,000 is to be used, the wires are certainly not to be meddled with. At different points along the line there are circuit-breakers where sections of the road can be de-energized. In case of a fire where a stream of water might be directed against the wires, or any other emergency, word would be sent to the Cos Cob power house, and in five minutes that section of the line would be de-energized. While no harm can come merely from the spray occasioned by squirting at a fire, it would certainly be careless for the firemen to direct a stream full at the wires. About two thousand "Live Wires," "Danger" and "Keep Off" signs have been installed along the line.

The Most Powerful Magnet.—Probably the strongest electromagnet is produced on the new method which Profs. Perot and Deslandres are applying, with success. Their idea is to take one of the strong electromagnets of laboratory type with pointed pole-pieces which already give a high value of the magnetic field, and then to put an extra coil around the air-gap between the poles so as to add considerably to the field. Such coil is made of thin copper strip and is cooled down as low as —30 deg. Cent. by a current of oil, so that a remarkably heavy current can be put into the coil without burning it; for instance, it will stand a current density of 1,800 amperes per square millimeter, using a 0.2 millimeter strip. Such a coil is put on a Weiss electromagnet which carries the usual coils and gives 41,000 gauss for the magnetic field strength. Putting on the 30,000 ampere-turns of the new coil, this brought the field strength up to 51,000 gauss, and it was only lack of current supply that prevented running as high as probably 60,000 gauss, so that a most powerful field can be thus obtained.

Science

A Fine Collection of Meteorites has been acquired by the American Museum of Natural History, in New York, through the generosity of Mr. J. P. Morgan. This comprises the entire stock of meteorites which belonged to the unique establishment in Washington known as "Howell's Microcosm" at the time of Mr. Howell's death, and includes representatives of 54 falls, weighing in the aggregate about 220 pounds.

The Association of American Geographers at its last annual meeting adopted a plan of co-operation with the American Geographical Society, in accordance with which a joint research committee of the two organizations is to administer a joint research fund; a joint meeting of the two organizations is to be held in New York each Spring; the Association is to publish its annals in collaboration with the Society, and the two organizations will interchange publications.

Explorations North of Siberia will be resumed this Summer by Capt. (late Lieut.) Vilkitskii, who discovered last Summer a large and previously unknown land north of Cape Chelyuskin. He will have under his command the same vessels as last year, the "Taimyr" and "Vaigach," both of which are ice-breakers. The best of the several maps thus far published of Vilkitskii's discoveries appears in the April, 1914, number of *Petermanns Mitteilungen*.

Sir Ernest Shackleton, accompanied by five members of his prospective Antarctic expedition, will shortly make a practice trip over the Norwegian glaciers, in order to test under polar conditions his rations, tents, motor-sledges, and other items of outfit. The party will live on regular sledging rations, and the effects of these on the explorers will be carefully studied. The dogs which Shackleton will take with him to the Antarctic have been especially bred in arctic Canada, and are a cross between a wolf and a Scotch staghound. They are about twice as heavy as those which he used in his last expedition.

Arsenic in Carpets.—Arsenic in certain carpets was found to be the cause of hitherto undiscovered maladies in various cases noted by the German scientist, Dr. Küttner. It may appear singular that the presence of carpets should be detrimental to the health, but he observed five cases with distinct symptoms of anæmia and the like, and these disappeared when the carpets were removed. He surmised from the color that the carpets might contain arsenic, and when they were analyzed this was found to be true, and in a considerable proportion. Traces of arsenic were also found in the bodies of the persons.

The Proposed Swedish Antarctic Expedition has now, as appears from a detailed statement of its plans in the *Geographical Journal*, expanded into an "Anglo-Swedish" expedition. Funds toward the support of the enterprise are being raised in England. The trustees of the British Museum have promised an annual grant of $2,500 for five years, and the Royal Society has granted $2,500 for the first year. Two places on the staff of the expedition are to be reserved for English scientists, and the collections are to be divided between English and Swedish museums. It is planned to have the expedition leave Europe in August, 1915, and return in February, 1920

The Members of the Staff of Mount Rose Observatory, Nevada, have found shellac to be an impervious and pliable water-proofing for rubbers, which otherwise during a day's use on the snow-fields absorb sufficient moisture from the snow to dampen the feet. An application of the shellac at infrequent intervals kept the rubbers in perfect condition. It was also found that a coating of shellac on the thongs of snowshoes prevented them from becoming quickly water-soaked on wet snow, and so eliminated much of the sagging and heaviness that form a serious drawback to walking on webbed snowshoes over melting snow. Thongs coated with shellac also dried after becoming wet much more quickly than thongs uncoated.

The Tides of Hudson Bay were discussed by Dr. Bell Dawson in a recent lecture before the Royal Astronomical Society of Canada. This subject is becoming of much practical interest, in view of the increasing use of Hudson Bay as a highway of commerce, but comparatively few actual observations have been made. The most important were those of Ashe, Stupart, Tyrell, McKenzie and others in 1884–86, in various shallow regions of the bay and in Hudson Strait. From these observations, the types and ranges of the tides are known at various present and prospective ports, and by selecting a port in some other part of the world for which the type is similar and for which accurate tide-tables exist, it is possible to compute tables for any desired port. By this method, Dr Dawson has computed tables for Port Nelson, using the tables for Bremerhaven, Germany, as a standard—both places having tides of the estuary type, and the North Sea and Hudson Bay being similar offshoots of the North Atlantic. In the same way, the tide-tables of Harwich, Eng., have been used in the computations for Churchill; while the tides of St. John, N. B., have been harmonized with those of Hudson Strait observed in 1884–86.

Aeronautics

Gyratory Control in Flying Machines.—Patent No. 1,096,045, to Gustav Mees, of Charlottenburg, Germany, is for a flying machine in which use is made of a steering lifting propeller combined with a fly-wheel acting as a gyratory body.

The Aerodynamic Institute of Koutchino, in Russia, celebrated its tenth birthday on May 10th. This institution was founded by its present director, M. Riabouchinsky, and has made notable contributions to the development of aeronautics

An Armored Aerial Machine.—Paul Daimler, of Cannstatt, Germany, has patented an armored aerial machine, No 1,095,711, in which aim may be taken and a projectile fired in the direction of the propeller shaft without hindrance from or interference with the propeller.

A Bomb to Destroy Aircraft.—A patent, No 1,092,760, to Joseph A. Steinmetz of Philadelphia, Pa , furnishes means for destroying an airship by another higher ship through the aid of a drag line carried by the higher ship and suspending a bomb which is exploded by being drawn upward alongside of and against the lower ship

A Flying Machine Control Device.—William B Oliver, of Collingswood, N J , in a patent, No 1,096,263, provides means whereby he seeks to automatically maintain the normal equilibrium of a flying machine in a predetermined position or series of positions during flight, thus relieving the aviator from the necessity of constantly manipulating the regulating devices.

The Wright Licenses.—According to the daily press, Orville Wright and the directors of the Wright Company recently met in New York city to discuss the terms upon which fliers and builders of aeroplanes may use the Wright inventions. In order to discourage bad workmanship, it is stated that only responsible firms will be licensed

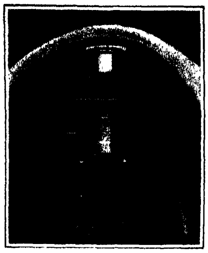
Using a Parachute for Elevating the Machine. In a patent, No. 1,093,788, V A Lamare, of Chicago, Ill , assignor of one half to Linwood F Jordan, of Portland, Me., shows a series of parachute reciprocating vertically in the frame of a machine with the upward and downward movement of the parachutes alternating to cause the ascent of the machine.

A Series of Flying Machine Patents.—James S. Lang, of Boston, Mass , has secured patents Nos 1,096,251 to 1,096,256, inclusive, the first four patents relating to gyroscopic controlling elements and some of the patents refer to the engine itself as the gyroscopic power, while patent No. 1,096,255 provides auxiliary planes at opposite sides of the machine and co-operating with the main plane for effecting a lateral control by varying the lifting efficiency of the main plane, and patent No 1,096,256 provides a special construction of one of the planes.

Military Aviation in the United States.—The United States Government intends to strengthen the aeronautical branch of the Army It is reported that an order for thirty aeroplanes has either actually been given, or will be given. According to Secretary of War Garrison, the army needs fliers badly The United States has made no systematic effort either to upbuild an air fleet at all comparable with the air fleets of Europe, or to train an aeronautic personnel The army aviation schools turn out but very few men.

Aviation in Japan.—Capt Tokugawa of the Japanese army, and an old pupil of Farman, has published an interesting article on the progress of aviation in his country For several centuries, the art of traveling in the air has been known to the Japanese, he claims In 1702, an ingenious bandit named Kakinoki Kinsuke invented an apparatus by means of which he was enabled to attain the roof of a building in Nagoya and rob it of certain gold ornaments As in Europe, aviation has become strictly military in Japan, the 25 aviators of Japan all belong to the army, which, up to the present, only possesses 15 aeroplanes, nearly all of which are of the Farman type Capt Tokugawa remarks that at small distances from the ground in Japan dangerous currents are constantly circulating, a fact which compels the Japanese aviators to fly always at a good height.

New Military Aeroplanes. At the military aerodrome of Doeberitz, Germany, trials are soon to be made with a mitrailleuse mounted on an aeroplane by the use of a turntable base so as to point the gun in all directions A special device is said to be employed so as to prevent the screw from being damaged by a projectile. The bottom of the aeroplane can also be opened up so as to allow of firing downward upon the ground On the other hand, we learn that the Admiralty has lately made very successful tests of a new hydro-aeroplane constructed by the Samuel White establishment. When carrying full load the speed was 75 miles an hour and it could rise from the water to 1,000 feet height in 2½ minutes. The flier is fitted with a Salmson motor of 200 horse-power size During the recent elimination flights which served to select fliers for the Swiss army, three types of aeroplane were qualified, namely, a Blériot and two German makes.

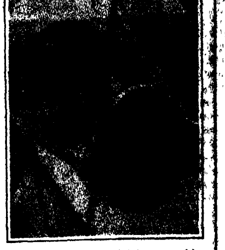


How the gun in the Vickers machine looks to the gunner.

Novelties in Aeroplane Design

A Sixty-Mile-an-Hour Gun-Carrying Biplane of Steel

A Flying Machine Which is a Mechanical Equivalent of a Soaring Bird



The gunner in the Vickers machine sits in front of the pilot.

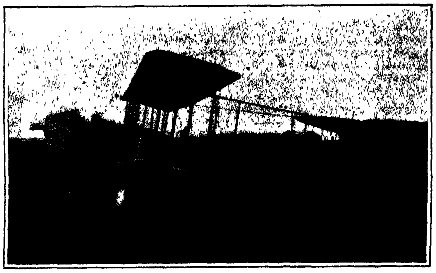
A Gun-carrying Biplane

By Major H. Bannerman-Phillips

UP to the present progress in aeronautics, from the military point of view, has been directed mainly toward obtaining the best possible method of aerial transport for purposes of reconnaissance, although the question of offense, by means of guns and dropped projectiles, has not been lost sight of, and many experiments have been made with both airships and aeroplanes, though with results which can hardly be called conclusive, in so far as they concern fighting in the air between aircraft. There are many who still hold that the business of the latter is scouting, and that, for the present at any rate, speed is more essential than ability to attack, since the fast light scout will have the advantage of the armed machine, which, having to carry a gunner besides guns and ammunition, is bound to be heavy and slow in pursuit, and will not be able to get within range of the fugitive, the single occupant of which will obtain all the information which it is possible for an overhead observer to get, in spite of threatened opposition.

Others again hold that the opposition of the fighting aeroplane will be effective to prevent other aircraft from prosecuting a successful reconnaissance, and that, if information is to be obtained, it will have to be fought for in the air.

The fighting aeroplane is being evolved to suit the latter view, and, although we have nothing definite, in the way of past experience, to go upon, it is none the less interesting to watch the evolution of the avowedly militant types of aircraft which are now being built, and which are especially designed to carry a gun, and one of these is the Vickers fighting biplane, which is shown in the accompanying illustrations It is designed for weight carrying and for a variable speed of from 40 to 70 miles per hour. The machine, so far as tests show up to date, has flown at speeds varying between 45 and 60 miles per hour Messrs Vickers, Limited, as a large armament firm, have every reason to know the value of steel in construction, and they have used it throughout in building this biplane, except as regards the main wing spars and two wooden struts in the landing carriage, the reason for this being that, although wood is not actually more elastic than steel, it will, in practice, bend to a greater extent and spring back again, without acquiring a permanent "set" In the later type of this machine, stabilizing flaps are used on the wings, instead of warping the whole wing. The gun is a small Vickers automatic gun, covered in front by a hemispherical shield, which is mounted on the barrel and moves with it The shield is provided with mica windows, to protect the gunner's eye from the draught of wind caused by the rapid movement of the machine through the air. The muzzle projects through the nose of the fuselage, which itself is entirely covered in, and is carried well forward of the wings. Those who understand the handling of such a gun will appreciate the fact that this is an ideal position for it, affording the utmost obtainable range of view and facility for traversing right and left, and for elevation and depression. This gun-position of course, involves the necessity for the biplane itself to be of the "pusher" and not of the "tractor" type.



The new Vickers gun-carrying biplane.

The requirements of the British military authorities are complied with, namely, that the machine gun shall have a clear field of fire in every direction up to 30 degrees from the line of flight, or, in other words, that the man behind the gun should be able to fire directly ahead within an arc of 60 degrees.

Analytical Comparison of the Bird and Monoplane

By James F. Blanchard, D.O., M.D.

FROM the dawn of time man's greatest desire has been to follow the birds through space; but not until the present gasoline motor made its appearance has that longing been realized.

If the minds that developed these wonderful machines which carry us through the air like the birds had kept away from the box-kite idea and followed more closely the anatomy of our feathered friends, the writer (who, by the way, is a physician, but one who has spent considerable time along mechanical lines) believes that more rapid progress would have been made in both pleasure and commercial air-craft.

His interest was greatly stimulated along these lines while spending a winter in Florida, several years ago. The birds of that part particularly interested him, and from these came his inspiration to build more closely along Nature's lines. The gull furnished him with the thought for the water plane, and the buzzard the idea of the land craft. His experience with the anatomy and physiology of these creatures he applied to his experiment, and the results were very gratifying.

After months of exhaustive investigation it was found that the structure of the present-day machines was weak and contrary to the laws of Nature as represented by the original denizens of the air.

It was plain to see that the mechanical bird, to be a success, must be a duplicate of Nature's air-craft, and in order that success shall be obtained, the principles of physiology and anatomy must be applied to this structure.

Pressed steel in suitable form is substituted for the bony structure of the bird. This forms the fuselage, rear appendages, main planes, and landing chassis. Trussing of light steel-tubing and laminated wood give a fine substitute for muscles, tendons, and ligaments. Fireproof cloth, sheet steel, and aluminium take the place of skin and feathers. The motor and radiator are substituted for heart and lungs; water, gasoline, and the oiling system for the lymphatics and vascular system; steering-wheel and controls for the nervous system. The special senses are represented by searchlights, wireless, and an efficient aviator. The flexor surfaces of the wings and tail-appendages are strengthened proportionally to extensor surface, according to the functions they have to perform. In this construction, strength and lightness are

The New Cunarder "Aquitania"

Another Ocean Liner Over 900 Feet Long Reaches the Port of New York

RESIDENTS of the port of New York are receiving dramatic evidence, these days, of the growth of the transatlantic steamship. In our issue of two weeks ago we illustrated the second of the great ocean liners to exceed 900 feet in length, the "Vaterland;" this week we present illustrations of the latest ship of this type, the "Aquitania," whose length of deck is 901 feet. As one contemplates the truly enormous dimensions of these vessels, reads the statistics of their cost of construction and operation, and takes a stroll through the vast halls, lounging rooms, and promenade spaces, the question inevitably arises: how can such costly ventures be made to return any dividend on the investment? The answer is to be found partly in the economic fact that the larger the ship, the less the cost of carrying a ton of freight or a given number of passengers, and partly in the fact that the possession of these wonderful ships enhances the reputation of the steamship company and so, indirectly, brings revenue into the treasury.

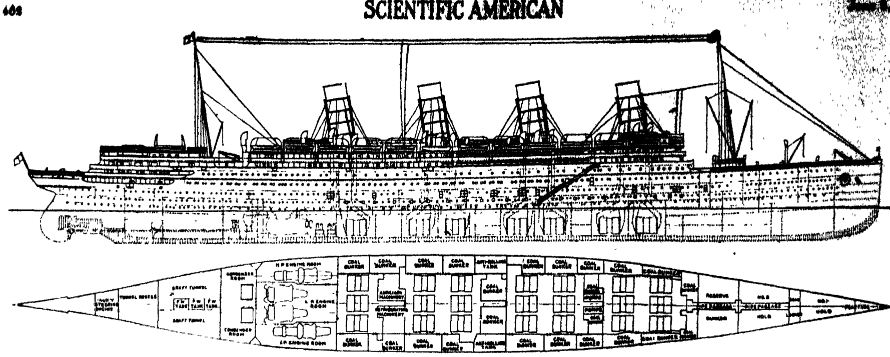
The "Aquitania," which was built at Clydebank, is exactly 901 feet long on deck, 97 feet broad, 92 feet deep to the boat deck, and has a gross tonnage of 47,000 tons and accommodations for between four and five thousand persons. It is an interesting historical fact that, a little more than a century ago, the same waters into which the "Aquitania" was launched witnessed the launch of the pioneer steamship in European waters--Bell's "Comet," which was launched in 1812. This tiny vessel was 42 feet long, 11 feet broad, and 5½ feet deep. It was a few years earlier that Fulton sent the "Clermont" on her maiden trip from New York to Albany and back on the Hudson River.

The "Aquitania," which is considerably the largest ship of the Cunard Line, naturally invites comparison with those two famous boats, the "Lusitania" and "Mauretania." Comparing her with the "Mauretania," we find that she is considerably larger, having a displacement of 53,000 tons on a draft of 36 feet, as against the "Mauretania's" 41,550 tons on a draft of 36 feet 2½ inches. Her horse-power and speed, however, are considerably less, the "Mauretania" having maintained an average speed of 26.06 knots across the Atlantic, with a shaft horse-power of about 74,000, whereas the "Aquitania" was designed to make 23 knots with 56,000 horse-power. However, it should be stated that, during her trial trip, previous to leaving for New York, she made considerably over 24 knots, with a proportionate increase in horse-power, without having her boiler plant pushed to the full limit. The "Mauretania" is 790 feet long on deck, 87 feet 6 inches in beam, and she has a molded depth of 60 feet 6 inches, as against a molded depth of 64 feet 6 inches in the "Aquitania." The gross tonnage of the "Aquitania" is 47,000 and of the "Mauretania" 30,704 tons. The hull of the "Aquitania" weighs 29,150 tons, and the machinery 9,000 tons, as against 19,758 tons' weight of hull in the "Mauretania" and a weight of machinery of 9,402 tons The "Aquitania" carries 6,000 tons of coal in her bunkers, and the "Mauretania" 6,354 tons The "Aquitania" has provisions and accommodations for 618 first-class, 614 second-class, 1,998 third-class passengers, and a crew of 972, making a total of 4,202 persons, as against the total number of persons carried on the "Mauretania" of 3,000 It may be mentioned that these figures were given by the designer of the ship, Mr. L. Peskett, in a paper read recently before the Institution of Naval Architects They are of great interest, as showing that to secure the additional three knots of speed the smaller "Mauretania" requires a greater weight of machinery than the "Aquitania."

Before passing on to further description of the technical features of the ship, mention should be made of those decorative features which form such an impor-

The first-class smoking room.

The restaurant.



Outboard profile and hold plan of the "Aquitania."

tant element of attractiveness in these great ocean liners. The scheme of internal decoration of the "Aquitania" tells the traveler the history of the nation from the far-off days when that "goodlie ship The *Great Harry*" was one of the world's wonders down to the end of Europe's struggles for supremacy with Napoleon, the period in which Fulton in America and Bell in Great Britain introduced the steamship to their respective countries. The sculptor, the painter, and the engraver have been requisitioned for this work, and the ship is full of rich samples of their work. Among the features provided for the recreation of the passengers may be mentioned the long gallery, which reaches for about 150 feet, and the garden lounge, extending for an equal distance. In the latter, sheltered from wind and weather, with an outlook toward the sea, the treatment is suggestive of an old English garden, the walls of the deck house on one side of the lounge having been treated to represent stone covered with trellis in natural teak. The ship has a large gymnasium and a swimming tank with a depth of 7½ feet.

Construction of the Hull.—There is a double bottom, extending entirely from stem to stern, generally 5 feet 4 inches deep, but increased to 6 feet 3 inches at the turbine room. In this double bottom are forty-one watertight compartments. The central longitudinal girder is built of plates over one inch thick, and this, with two other fore-and-aft girders on each side of it, are solid and watertight. The side framing is of steel channels, with webbed frames 36 inches deep introduced at every third frame throughout the greater part of the length of the ship. All of these extend to a deck 10 feet above the load water-line, and some to decks above this level. The shell plating is 23/20 of an inch thick amidships, the four sheer-strakes being doubled.

Subdivision.—The hull is divided into eighty-four compartments in addition to the forty-one compartments in the double bottom. There are sixteen transverse bulkheads, most of which extend to 19 feet above the load water-line. The turbine room is divided into three compartments by two longitudinal bulkheads, and there is a centerline bulkhead running through the room containing the condensing plant. Eighteen feet in from the outer skin of the ship, on each side, are longitudinal bulkheads forming the inner walls of the bunkers. These extend throughout the machinery and boiler spaces and afford an inner skin to prevent the inrush of water, in case of accident, into the boiler spaces. The hatches to the cargo hold are trunked and made watertight to the weather deck. In her construction the ship may be considered as a box girder formed by the double bottom and the side framing and shell plating, the top of the girder being what is known as B deck, 73 feet from the keel-plate. The shell plating is doubled for a height of 12 feet at the gunwale. For the remaining part of the girder this deck is single-plated. Fore and aft of the machinery spaces is a partial deck, making six within the molded structure of the ship, and there are three superstructure decks above this, making nine in all.

The "Aquitania" carriers 80 large lifeboats, including two motorboats, which are described elsewhere in this issue. For clearing the ship of water, in the event of flooding consequent on collision, pumping arrangements have been provided for dealing with about 16,000 tons of water per hour.

The boiler plant consists of twenty-one, large, double-ended boilers, capable of converting 9,000 tons of water into steam per day. They are operated under a pressure of 195 pounds to the square inch. The ship has four elliptical funnels measuring 24 feet by 17 feet in diameter, and the distance from the top of the funnel to the level of the fire grate in the boiler room is 160 feet.

The turbines are directly coupled to the propellers, and there are four in all, placed in separate watertight compartments. They are operated on the triple-compound system, which gives a great range of expansion to the steam, with consequent high economy. The condensers are filled with 18,700 tubes, which, if placed end to end, would extend for 50 miles, and through the condensers 12,500 tons of water pass per hour for the condensation of the steam. There are over 1,000,000 blades in the turbines, which vary in height from 1½ to 20 inches.

The "Aquitania" has the same beautiful contour and well-balanced position of masts, funnels, deck-houses, etc., which characterizes the "Lusitania" and "Mauretania."

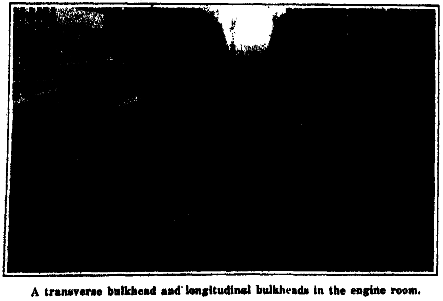
Testing the Langley Aeroplane at the Curtiss Aerodrome

By Our Staff Correspondent at Hammondsport

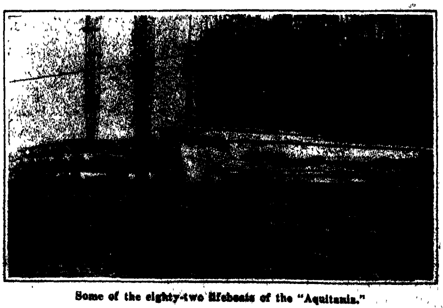
As this goes to press, Mr. Glenn H. Curtiss is on the point of launching the large Langley aeroplane at his aerodrome on the shore of Lake Keuka. The machine and its engine had been shipped from the Smithsonian Institution to the Curtiss factory early in April, and was reclothed without change of size or shape. The framing, the engine, propellers, wings, rudders, and controls are, therefore, just as Langley left them. A modern radiator and carbureter are used, and the whole aeroplane is mounted on three floats, so as to rise from the water. In this way over 200 pounds' extra weight and considerable air resistance have been added to the original machine. With the lowered mass center and lowered line of resistance, the craft is really less steady than the original; yet it is expected to navigate without presenting aerodynamic difficulties. The practical aviators expect it to succeed on the first launching.

For some weeks past the aeroplane has been in the process of re-covering, assembling, taking on floats, and the framework that joins them to the original frame. The whole was suspended by four parallel ropes, as in Langley's day, from the ceiling of the workshop, and moored to the wall by a spring balance attached to its tail. The engine, of some 50 horse-power, set the twin propellers, of 8 feet diameter and 8 feet pitch, whirling at over 600 revolutions per minute, and registered a thrust of 300 to 400 pounds. In the open air, it is expected, the thrust will exceed 400 pounds. This thrust should easily sustain the 830 pounds original weight of the machine, plus the 200, or a little more, due to the hydroaeroplane floats and the trussing above them. As the total wing area equals 1,024 square feet, the whole should lift at a speed neighboring 25 miles an hour.

On the evening of May 28th, the aeroplane, minus wings and tail, was transported to the Curtiss aerodrome, placed on the beach, and adjusted for a preliminary skim on the surface of the lake. A thunderstorm blew up and raged till midnight. Next forenoon the wingless craft was carried from the hangar, set on the water, and started, with Mr. Curtiss as pilot in the little canoe-shaped seat where Manly sat in 1903, when he was shot so heroically into space from the top of the house-boat, then headlong beneath the Potomac waters. Langley's successor and friend, Secretary Walcott of the Smithsonian Institution, now stood near, a complacent and smiling spectator. About him was a little army of aviators and assistants; at his elbow stood his daughter, the keenest spectator of all. The cameras began to click, the craft shot over the water at a 40-mile pace, skimming like a stone, and almost leaping into the air. The small vertical air rudder under the rear center of the frame had not purchase enough to enable Curtiss to turn promptly on the water; so he stopped his engine nearly a quarter of a mile from shore, and allowed a motor-boat to tow him home without delay.



A transverse bulkhead and longitudinal bulkheads in the engine room.



Some of the eighty-two lifeboats of the "Aquitania."

This picturesque and successful run inspired everyone with the belief that, with the wings added, the craft would take to the air well enough to satisfy a moving-picture artist. Some final adjustment was now made in the bevel-gears connecting the engine and propeller shafts, and announcement was made that the real launching would follow presently, if the weather permitted; for heavy clouds were gathering, and it was very moist and hot. An hour later a furious thunder-squall broke over the aerodrome, and the men laughingly remarked that the demons of the air still rage at Langley's invention, and want to destroy his machine.

As the sky threatened during the rest of the day, Mr. Curtiss postponed the launching till the next morning. At sunrise on May 28th, the workmen began fixing the wings on the frame beside the lake, and at six o'clock all was ready. Though the clear sky and mildly moving air seemed most inviting, Mr. Curtiss hesitated to launch, owing to the streaked condition of the water, which indicated a puffy and treacherous air. At seven he took the pilot's wheel, headed in the direction from which the wind appeared to come, and skimmed over the water under full power. The motion was most stately and dignified, but the craft stubbornly veered to port, while Curtiss tried to steer straight ahead with the little vertical rudder. The great tail automatically headed her into the wind from the port side. Presently she rose on even keel, without pitching or rocking, and sailed toward the beach. Mr. Curtiss, erroneously thinking the left side had too much resistance, shut off the power, and was towed back to the hangar. Unfortunately, neither the photographer nor the moving camera man caught the craft in the air. A second launching, after breakfast, terminated prematurely by the giving way of one bearing of the port propeller shaft near the bevel gear, entailing some hours delay for repairs.

Langley's creation is the favorite machine in the factory, even when compared with the transatlantic flier which is building in the neighboring room. The mechanics express astonishment at the perfection of design and workmanship displayed in every part of the old Langley structure. They have been working long hours overtime, for many days, yet each mechanician is as keenly interested and enthusiastic as if the machine were his own. The propulsion plant they regard as a marvel for that early day, 1903—five years before the beginning of public flights in this country and Europe. The brief successful flight of May 28th proved Langley's invention to have been the first machine in history capable of prolonged free flight with a passenger. A great scientist and inventor, misunderstood and persecuted in his lifetime, is vindicated.

The Bachelet Railway

THE Bachelet Railway, with which readers of the SCIENTIFIC AMERICAN are doubtless familiar, since the invention was described in these columns many months ago, has caused some stir in England. Bachelet recently exhibited there the miniature prototype of a 300-mile an hour train. Yet Englishmen, while astonished at the performances of the model, were not blinded, as the following excerpt from the *Manchester Guardian* shows

"First," remarks our contemporary, "it is an electric railway; but instead of rotary electric motors in the coaches, there are large electromagnets encircling the track at regular intervals, whose function it is to pull the train or coach along, automatic switch-gear cutting in and out each solenoid at the right moment. That this is easily workable for a small model and quite practicable for a full-sized railway is obvious enough; but on the face of it it should be far from economical, even if each solenoid is energized only while a coach is actually within its tunnel, and the air-gap reduced to a minimum. Taking this economical precaution would mean that the coach has to carry in one form or another an armature sufficiently heavy to give the required average pull, though attracted only for a comparatively short proportion of the time occupied by the whole run. As against this—or, at least, one may so consider, though the published accounts do not say so—is the second great feature of supporting the train magnetically in the air. This gets rid entirely of the ordinary rail and journal friction, and so the train might be made as heavy as its peculiar method of propulsion called for without any increased frictional loss, so long as the size or shape was not altered to increase the wind resistance. This alone, under the best conditions, would be enormous at 300 miles an hour; but that is not a greater argument against the Bachelet railway than against any other kind of locomotion at that speed.

"As to the exact method of supporting the coaches we have not much information; but we surmise that the physics of it are nothing more novel than electromagnetic repulsion. When a coil of wire having no self-inductance is placed in an alternating magnetic field, so that the lines of force pass through its turns, an alternating E. M. F. is set up in it at 90 degrees in phase behind the magnetic flux, and, the resultant current in the coil being in quadrature with the flux, the forces between magnet and coil cancel out to zero. The coil, therefore, would make no effort to move. But the ideal of no self-inductance is unattainable in a coil or even in a flat disk (such as M. Bachelet appears to have used to impress his methods on the minds of journalists and others), and, as a result, the current lags by more than 90 degrees behind the magnetism, and the repulsion force predominates to that extent. All this, so far from being new, was stated and explained by Prof. Elihu Thompson long ago, and is the basis of the repulsion motor, which is wasteful, heavy, and expensive. By using a powerful alternating current magnet with, preferably, a high frequency, metal rings and disks of considerable weight may be supported and flung up in the air; and the lower the resistance the greater the effect, because the induced current is greater. Hence, presumably, the disk form. There is reference in the newspaper accounts to other auxiliary apparatus, but too vague to disclose whether this apparatus is calculated materially to improve the economic efficiency of this method of supporting a train. Unless it does, the Bachelet railway's chief claim on the future historian may be that Mr. Winston Churchill went to see it."

The Death of Sir Joseph Swan

SIR JOSEPH WILSON SWAN, inventor of the first incandescent electric lamp, died on May 27th at the age of eighty-six.

Although years of patent litigation have upheld Edison's right to be regarded as the inventor of the carbon incandescent lamp, there can be no doubt that Swan was entitled to a place among the first two or three who gave to the world the present incandescent lighting system. He early showed a marked bent for scientific pursuits, and was accordingly apprenticed to a chemist in his native town. Thence he went to Newcastle, where he was employed in a large house of manufacturing chemists, in which he became in time a partner.

As a manufacturer, Swan was engaged in the production, among many other things, of photographic plates. The dry plates of that time were slow, and instantaneous photography was impossible. Swan experimented, with the purpose of increasing the sensitiveness and rapidity of the plates, and eventually produced the first really rapid dry plates A valuable pendant to this great achievement was his subsequent invention of carbon printing in photography.

As early as 1860 Swan became convinced that for most purposes the incandescence of a filament, probably of carbon, would be the most practicable source of illumination.

His first electric lamp had a carbon filament which he made by packing a strip of thin cardboard with powdered charcoal in a crucible and subjecting it to intense heat. This was placed in a glass bulb from which the air was exhausted, and an electric current was applied. It will be observed that this was practically the same method that Edison employed in his early operations at Menlo Park in the late '70s. Swan secured his current from a battery of Grove cells, which was not sufficiently powerful to cause complete incandescence, though the filament was heated red hot.

In 1879-1880 Edison gave his first exhibition of electric lighting at Menlo Park, with filaments of paper or bamboo carbonized through intense heat Late in 1880 Swan gave, at Newcastle, his first public exhibition of incandescent electric lighting on a large scale, using in his lamps filaments of cotton thread "parchmentized" by the action of sulphuric acid.

Another successful filament was made by him by squirting a jet of collodion into a coagulating solution, and then carbonizing by means of heat the tough thread thus produced. This process in modified form supplanted the Edison carbonized bamboo filament both in America and Europe.

The Current Supplement

IN this week's issue, No. 2005, of our SUPPLEMENT, H Onslow gives some interesting facts regarding the structure and composition of hairs and hair pigments. —The second Wright Memorial Lecture was delivered this year before the Royal United Service Institution by Dr. R. T. Glazebrook, the director of the National Physical Laboratory, London, England. It deals with the services rendered to aeronautics by experimental research, and is reproduced in full in our current issue. —Prof. H. Payne writes on insulation for cold storage.—Dr. M. Philippot contributes an article on legal time in various countries.—J. A. Seager describes one of the most important iron works in Austria.—M. Longridge analyses the various causes of breakdowns in stationary engines.—Dr. Eccles' review of recent patents in radio-telegraphy is continued, and will be concluded in our next issue.

Washington stands first in lumber production, with Louisiana second.

Misinterpreted Wireless Signals

To the Editor of the SCIENTIFIC AMERICAN:

In the correspondence column of the SCIENTIFIC AMERICAN dated May 16th, 1914, under "Wireless Distress Signals," the writer states that the signal S O S is quite dissimilar to M B S, but, to my way of thinking, the combination of M B S could more easily be mistaken for S O S than any other combination of letters.

If the operator at the receiving station puts the receivers on his head in the middle of the call M B S and the call is not properly spaced, as most calling is not, due to the loss of time, etc., it is a very easy matter to mistake the call and read it S O S, which it would make if the operator at the receiving station took the S to be the first character of the call.

This undoubtedly was the cause of the false S O S on the part of the receiving operator, and the reason the false reports were not stopped by the operator on the "Siberia" was due to the fact that he was out of receiving range of the shore station.

I believe it would be impossible to have any definite tone for distress calls, due to the fact that there are all the tones possible to produce by the different spark gaps and systems now in use To have a definite tone and keep it uniform on all sets would be an endless undertaking due to voltage fluctuation, damp condensers, and numerous causes R. W WILEY

San Francisco, Cal

Nomenclature of Food Values

To the Editor of the SCIENTIFIC AMERICAN

Food values seem now, according to the current literature, to be classed as "energizers," "calories," "units of energy," "heat-giving qualities," etc, etc, little being said about the upbuilders.

The human body is an engine of flesh and blood and, of course, food keeps the engine going, and it is frequently popularly regarded as of steam propelling force value only We put coal in the furnace and about one seventh of its energy is passed on to the engine, the balance goes up the chimney This steam keeps the engine going, but the moment wear and tear, erosion, friction, etc, impairing the brasses, causing the cylinder to wear or the crank-shaft to need repairing, etc., the steam having no upkeeping, building, repairing influence whatever, trouble results. If the mechanic be not called in, no matter how much steam the gauge on the boiler shows, the engine rocks, pounds, runs down, and the steam becomes of no value The engine stops, because it is out of repair, and demands that new parts either be supplied or other worn deficiencies be made whole

And this is where the mechanical properties of the two bodies, the steam engine and the human engine, differ, as to energy influences.

Butter has two and a half times the energizing power of, say, lean meat or the casein of milk, the moisture being equal. Theoretically, on a full meal of butter or olive oil, we should be able to do two and a half times the work that a full meal of meat, or beans, or bread would produce. Butter would be a highly energizing food for the body, but prove worthless as an upbuilder, a repairer of the waste constantly going on with every breath inhaled—exhaled because of its lack of protein content. The same rule holds good with starch and sugar, carbohydrates, heat-givers or producers But in valuing up foods, whether all protein (building) or partly protein and partly fat and carbohydrates, the *energizing* value of the food only seems to be the index The protein is also an energizer, lean steak having, presumably, on an average, 950 units of energy to the pound Macaroni, the genuine American made article from our northwestern-grown Autumn wheat, so rich in gluten and natural sugar, "macaroni wheat," is credited with 1,650 calories of energy

But lean meat is, ex the moisture, almost wholly protein, while in macaroni, containing from 12 to 14 per cent of protein, the balance is made up of carbohydrates, starch and sugar, and for that reason one could keep in better health on a protracted diet of macaroni than on lean meat There is an approximate food balance in macaroni, but no balance in the lean of meat Potatoes, with a credit of 295 calories energy, contain but 1 8/10 per cent protein, while lettuce, with but 65 calories, has but 1 per cent protein

So it would seem that when food values are expressed in energies, reference should invariably be made to the upbuilding as well as the heat-giving values There is more, therefore, than the energy values in food, and whether the proteins are properly balanced with the carbohydrates and fats is of grave moment, indeed

Weaving Real Persian Rugs on a Power Loom

An Interesting Solution of a Difficult Mechanical Problem

By Theodore G. Hoster

FOR centuries the hand-woven Oriental rugs, and notably the Persian pile rugs, that is, rugs having a pile formed by Persian or Sehna knots, have been admired the world over for their beauty in design and color blending, and prized for their durability Many attempts have been made by inventors to weave a Persian rug on a power loom to supersede the tedious process of hand-knotting as practised by the Oriental weavers The attempts have failed, because the ordinary power loom for weaving carpets and rugs can weave only in a forward direction, while for making a Persian or Sehna knot, a partial return weaving motion is apparently required

This can best be explained by references to Figs. 1 and 2, of which Fig 1 illustrates an ordinary pile fabric having each pile *a* looped around a single warp or a weft *b*, and Fig 2 shows a Persian rug having the pile thread *a'* passing under one warp *b'*, then up between the warps *b*¹ and *b*², completely around the warp *b*², and up between the two warps, *b*¹, *b*² It will be noticed that the full loop around the warp *b*² requires a backward movement, and this the ordinary power loom cannot do As a matter of fact, it has been considered by experienced weavers an impossibility to make the Persian or Sehna knot, shown in Fig 2, successfully on a power loom. The durability of the weave of the Oriental pile rug over the ordinary pile carpet or rug, considering the pile material to be alike, can be readily demonstrated by reference to Figs. 1 and 2 A pull exerted on either pile end of the knot shown in Fig. 1 draws the pile out of the body of the fabric, while a pull exerted on either pile end of the Persian knot, shown in Fig. 2, draws the knot tighter For this reason it is not necessary to use extra binding threads to hold the Persian knots in place in the weave, as is required in pile fabrics having the pile threads shown in Fig. 1.

Let us now briefly describe the weaving of an Oriental rug by hand In weaving, or, rather, knotting a Persian rug, the Oriental weavers are squatted in front of a vertically disposed warp depending from an overhead warp beam, as depicted in one of our illustrations. Each weaver, with his or her fingers, deftly ties a knot on a pair of warps (as shown in Fig. 2), the yarn used corresponding in color with this particular part of the design Next the weaver ties another knot alongside the previous one, on the following two warps. This knotting process is repeated until the weaver reaches the beginning of the row of knots made by his neighbor. Each weaver has a range of about two feet, in a horizontal direction. To tie a single Persian knot requires five distinct finger motions. After a row of knots has been completed a tying weft is threaded on the warp, and the knots and weft are beaten home. The balls of differently colored yarns for the knots are suspended from above, and the weaver cuts off the yarn after each knot is made. In front of each weaver and attached to the warps, a distance above the working row of knots, is a slip of paper (known as the *talim* sheet), which contains the instructions as to the color of the yarns to be used for each knot in each row of knots These instructions are compiled by special writers from the original design made by a draftsman, but some weavers are skilled enough to evolve a design while weaving a rug, that is, follow their own intuition and produce rugs marvelous in color blending and figuration. The piles are, naturally, of unequal length, and after the rug is woven the pile is sheared to uniform length. That the painstaking Oriental weavers, with the crude means at their command, have been able to produce the wonderful rugs so well known to us all, is truly marvelous.

Although the weave of Oriental rugs has been well known in Europe and America for centuries, although the power loom of Cartwright has been in use since 1784, and although the Jacquard machine for mechanically reproducing the most intricate patterns has been in action since 1801, it remained for an Armenian inventor, James Karmi Dalkranian, of New York, to devise a loom for weaving an Oriental pile fabric having true Persian knots.

In order to accomplish this result, Mr. Dalkranian had to strike out on entirely new lines, which we will endeavor to make clear to the reader by reference to the diagrammatic Figs. 3, 4, 5, 6, and 7. In the loom the warp threads are stretched in pairs *a*, *a*¹ from the warp beam *b* to the fell of the fabric at the breast beam *c*, and are controlled up and down by heddles *d*, *d*¹ for periodically opening the shed for the introduction of the wefts or binding threads. Next to the heddles *d*, *d*¹ is a fixed reed *e* through which pass the warp threads, which receive a sidewise motion by shogging combs *f*, *f*¹ to permit of alternately crossing the normally parallel warp threads *a*, *a*¹ and returning them to parallel position between the reed *e* and the fell of the fabric. Next to the shogging combs *f*, *f*¹ is the intermittently reciprocating lay *g* for beating in the knots and the weft. A tuft yarn tube *h* having an up-and-down and a forward-and-backward movement is used for each pair of warp threads *a*, *a*¹ to tie a pile thread *i* of a particular color to the pair of warp threads *a*, *a*¹, and this tuft yarn tube *h* operates closely to the fell of the fabric and in front of the lay *g* whenever the latter is in rearmost inactive position. The movements of the several parts is controlled in the proper sequence by suitable mechanism driven from a main power-shaft. During the working of the loom the shogging combs *f*, *f*¹ alternately cross a pair of normally parallel warp threads *a*¹ and then return them to parallel position, and during this time the tuft yarn tube *h* passes twice between the warp threads *a*, *a*¹, once while the warp threads *a*, *a*¹ are in the crossed position, and once while they are in the parallel position.

Fig. 4 shows the warp threads *a*, *a*¹ crossed and the tuft yarn tube *h* returned to uppermost position after its first descent between the warp threads *a*, *a*¹, so that

(Concluded on page 472.)

A "Varsity" Electrical Show

AN electrical show was recently held at the Ohio State University which proved an unqualified success. It was given by an enterprising association of one hundred young men, constituting the Ohio State University Branch of the American Institute of Mechanical Engineers. A string of lights from the University entrance to the Electrical Building, an immense "Electrical Show" sign, an electric waving American flag, a string of arc lights about the eaves of the Electrical Building, and a large searchlight mounted upon the building, made known to passers-by that the Electrical Show was on. The show was divided into two parts, one devoted to the exposition of commercial appliances, while the other related more particularly to demonstrations of curious and novel electrical effects, such as experiments with high-tension high-frequency currents, frying eggs on ice with the aid of eddy current, demonstrations of wireless telegraph apparatus, the singing arc, the loud-speaking telephone, and the like. Local electrical manufacturers supported the show with exhibitions of apparatus. Altogether there were about forty exhibitors in that section. The fact that the receipts were three times as much as the expenses may be taken as a measure of the success of the show. All the standard features of an electrical show, such as given in New York or Chicago, were to be found on a smaller scale at this exposition.

A Gasoline Switching Engine

By Our Berlin Correspondent

THE odd little piece of mechanism tucked under the end of a freight car in the accompanying photograph is a 20 horse-power switching engine, designed by a German firm. To insure the necessary traction the "locomotor," as the little switching engine is called, is furnished with a jack which is operated to lift the platform of the freight car, thus increasing the weight on the tractor wheels, and hence their adhesion to the rails The jack is also fitted with means for coupling the locomotor to the car.

The chassis is made up of substantial angle and channel irons and rests on two sets of steel wheels running in roller bearings. It is so designed as to insure perfect protection as well as an easy access to all the main interior parts—motor, carbureter, radiator, fuel tank, gearing, bearings, control gears, etc. The motor is a vertical four-cylinder 20-25 horse-power combustion engine of the constructor's own design. The running wheels are driven through the gearing, chain-wheel and chains, levers serving to actuate the forward and backward steering, and to regulate the carbureter and speed gear, while pedals are used to throw the motor out of gear. All levers and pedals are operated by the driver, from his stand on the locomotor platform, or from the ground beside the vehicle. The locomotor is fitted with a capstan, driven direct from the gearing, and which serves mainly for the actuating of turntables

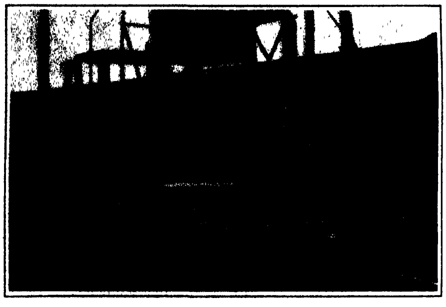
The uses of the locomotor are many. Being always ready to work at a moment's notice, and able, without any special manipulation, to travel in a forward or backward direction, it will convert any railway car into a motor coach, traveling along with it over turntables, operating these by the aid of its own capstan, hauling or pushing several cars at a time, loaded or empty, over any normal curves or gradients, and braking on a downhill course.

The locomotor is readily operated by one man and does not depend for the consumption of materials on the skill of the driver. There is no increase in consumption due to the weight of the engine itself, or the coal, water, steam, or accumulators carried. During intervals in operation there is no consumption of materials.

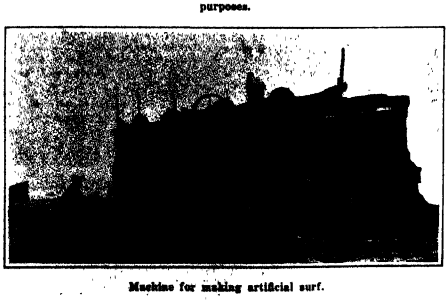
It is intended to fit the locomotor with transversal wheels, allowing of its leaving the track wherever desired, and travel from one track to another, thus avoiding any dead-end sidings or empty tracks, and insuring a considerable saving of time.

Electrical show at the Ohio State University.

Radio-equipped motor lifeboat for the "Aquitania."



Motor switching engine, utilizing the weight of a freight car for traction purposes.



Machine for making artificial surf.

Protection from Trichinosis has recently been investigated by the Bureau of Chemistry, with a view to establishing a basis for meat inspection requirements in regard to cooking pork products Experiments show that the trichinæ larvæ die after a brief exposure to a temperature between 53 deg and 55 deg Cent (127 40 to 131 deg Fahr) These temperatures are so low that one might expect very imperfect cooking to secure the desired result, It has been found, however, that the temperature in the interior of meat rises very slowly during the cooking process, and it is of course essential that the whole of the meat should be heated to a temperature high enough to destroy the parasites Tests for insuring a proper temperature have been devised, and will soon be put in operation in meat-packing establishments

Motor Lifeboats of the "Aquitania"

WHEN the passengers and crew of a vessel are forced to take to the lifeboats, if help does not arrive soon, the boats are apt to be so widely scattered that it is difficult for rescue ships to locate them A frightful illustration has only just been furnished us by a lifeboat that was picked up the other day with a few survivors two weeks after the other boats from the same wreck had been rescued No matter how good the lifeboat, it may fail in an emergency, because it possesses no means of propelling itself to safety and no means of communication with rescuers out of sight and hearing With this in mind, the owners of the "Aquitania" are furnishing that vessel with two large motor lifeboats fitted with wireless telegraph apparatus, these, of course, being additional to the regular lifeboat equipment. The motor boats are 30 feet long by 9 feet 6 inches wide They will be used to tow the ordinary lifeboats. The wireless apparatus has a range of 100 to 150 miles, which will enable them to keep in constant communication with steamers The boats are fitted with 4-cylinder, 30 horse-power motors, starting on gasoline and running on kerosene. The motor is well protected from storms by a closed compartment There is ample space for storage of blankets, medical stores, and other necessaries.

A Memorial to Jack Phillips, the chief wireless telegrapher on the "Titanic," is to be erected at his native town, Godalming, England It will take the form of a rectangular cloister of some 120 feet square, and will stand on glebe land near the parish church. The cloister style is a new form of memorial architecture in England, where it has been warmly approved by architects and art-lovers generally

Ocean Waves for Inland Resorts

THE odd-looking piece of machinery shown herewith is a wave-making machine It will make, to your liking, any one of a half dozen or more different kinds of waves Ocean waves, long rolling billows, short choppy waves, and, among others, the white-cap variety. It is possible to have a real Atlantic City surf just by switching on an electric motor, which sets the four plungers in motion These plungers work up and down in the water, and the different ways the plungers are worked make the different kinds of waves For instance, if long rolling billows are desired, the plungers are worked in unison If a short choppy sea is wanted, the plungers are worked independently of each other; when white-caps are wanted, two plungers are worked up and two down; this combination causes the waves to break into white-caps The different combinations of the plungers result in the different kinds of waves This unique mechanical device will be used at Summer resorts this season, on lakes that never saw a wavelet larger than a ripple.

How the Roots of Seedlings Write

Interesting Experiments for the Summer Season

By S. Leonard Bastin

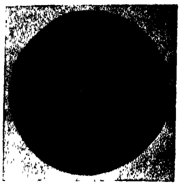
THE mystery of plant movement has always presented a problem of peculiar complexity to the botanist While the text-books discourse authoritatively upon the response of the protoplasmic matter in vegetable tissue to stimuli, the conscientious student is bound to confess that, after all, we know very little about the matter. The most that can be said is that certain parts of the plant may be expected to do certain things, because they have been endowed with a tendency in that direction Still, a very interesting line of study may be followed in connection with the movements of plants, and one which cannot fail to lead to instructive conclusions

It was believed by Darwin that all growing shoots were constantly on the move, to a greater or less degree This habit is seen to the most pronounced degree in the species with twining stems and in some of the Acacias where the leaves maintain a continuous rotary movement The name given by the great scientist to this phenomenon was circumnutation and it was to this feature that Darwin thought he could trace all kinds of plant movement -a theory which is not however generally accepted at the present time Perhaps even more interesting was the fact that it was discovered that a very similar movement is to be noticed in the roots of young seedlings In this direction it is possible to carry out a large number of most fascinating experiments indicating the curious and beautiful courses which the radicles of growing seeds will trace in the early stages of their history

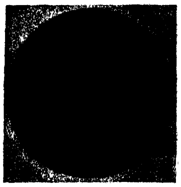
Probably one of the simplest devices by means of which the root movements of seedlings may be closely watched, is an ordinary photo printing frame These are, of course, very inexpensive, and answer all the purposes required Pieces of glass to fit the frames should be obtained, and for this purpose, of course, damaged negatives with the film cleaned away are exactly right It is also needful to obtain some pieces of very course canvas or fine netting, with a mesh through which the rootlets of the seedlings can easily force their way This material should be cut into pieces of such a size that they cover the frame, at the same time allowing for strips on either side to turn down A few tacks will complete the necessary things required for making the appliance for testing the root movements of seedlings The loose backs of the frames are now entirely dispensed with, and, as well, the clasps which hold down the hinged portion should be removed The next step is to place the frame face downward on a table and stretch the canvas across the back tightly, and holding it thus, fasten it down to the sides of the woodwork, as shown in the illustration It is important that the material should be pulled across quite tightly, as any sagging of the cloth is very undesirable

When the frames are completed, it is as well to start smoking the sheets of glass, in order that a suitable surface may be presented on which the seedlings may trace their movements. This may be accomplished in a variety of ways, but the best and simplest method is by using an ordinary candle. First of all make sure that the glass is quite clean and dry, and then taking it between the finger and thumb, hold it over the flame in a slanting fashion In order to get the greatest amount of smoke, the surface of the glass should just touch the top of the flame The glass should not be held for more than a second in any one position, as the heat will be likely to crack it, but if the sheet is kept moving about there will be no danger of breakage. Very soon the glass will become well clouded, but the process will not be complete until the surface is thickly coated with the smoke deposit, so that the slightest scratch will leave a sharp, clear mark. As each piece of glass is ready, this should be carefully stored away in a place of safety where there is no fear of damage being done, and also in a position sheltered from dust.

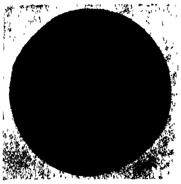
Almost any kinds of moderate-sized seeds are suitable for testing on the frames which have been prepared. Of course, very large kinds develop such big roots that these are unable to pass through the openings in the canvas, but putting these aside, there is an infinite variety in the subjects which may be tried. A peculiarity should here be noted in connection with the seeds of most leguminous species. Some small sorts of beans and peas have been tried, but it has been found quite impossible to induce them to trace their life history on the smoked surface. In most cases, before the tip of the radicle has reached the black surface, it has suddenly ceased growth and absolutely refused to push on downward to the impenetrable glass. This seems to indicate a perception which almost amounts to intelligence on the part of the radicle, giving yet further support to the theory that the tips of growing roots are as sensitive to their surroundings as are many of the organs of the lower animals. In order to make the experiments more interesting, an endeavor should be made to select as wide a variety of seeds as possible, so as to secure the greatest diversity in the records.



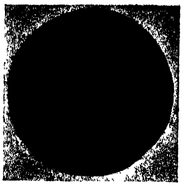
Seedlings of Centaurea cyanus.



Tracing by mustard roots.

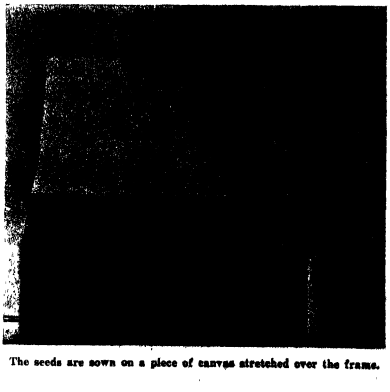


Cress root tracings. These are among the best obtainable.



Produced by seedlings of wallflower (cheiranthus).

The framework is made out of a photograph printing frame.



The seeds are sown on a piece of canvas stretched over the frame.

The best method of sowing the seed on the surface of the canvas is to sprinkle it over with a spoon. The thickness or otherwise of the sowing should be arranged according to the nature of the pattern required. If the seeds are sown very thinly, each one being quite isolated from its fellow, we shall obtain a record most interesting from a scientific point of view, in that the actual movements of the individual radicle are placed on record. On the other hand, designs of great complexity are secured by sowing the seeds very thickly on the surface of the canvas. As soon as the sowing is accomplished, a thorough drenching of water should be given to the seeds, and care taken to see that the canvas is quite wet. All seeds, of course, germinate more rapidly in the dark, and in this case it is a wise plan to cover them with a piece of thick cloth or wadding which has been previously saturated with water. This will not only keep away the light, but will also serve the purpose of conserving the moisture. Of course, on no account must the seeds be allowed to become dry, and in order to make this quite impossible, it is well to stand each frame in a dish containing about half an inch of water. By capillary attraction, the fluid is drawn up all over the canvas, and one can well go away and leave the seedlings for a day or so, provided an occasional glance is given to see that the water is maintained at a proper level. There is a wide difference in the time which seeds take to germinate. Some kinds, such as mustard, cress, and nearly all the cruciferous plants, start active growth in a few days, while other sorts will lie dormant for quite a long period. Of course, another feature which goes a long way to control the rate of growth of any seeds, is the temperature. During warm weather, or if the seeds are kept in a heated apartment in Winter, the development will be much more rapid than when the conditions surrounding the seeds are chilly.

As soon as the germination is once started a close watch should be kept on the underside of the canvas for the appearance of the rootlets. At the first sign of the radicles, measures must be taken to place the pieces of smoked glass underneath, as in many cases the movements are most pronounced of all during the first stages of growth. It will probably be desirable to make some arrangements whereby the smoked surface can be brought nearer to the roots, and some means of supporting it underneath with strips of wood is easily adopted. It is necessary to make certain that the smoked glass is quite unscratched, and also in placing it in position that it does not get marked in any way. To insure this, the glass should not be placed nearer than an eighth of an inch to the roots which are growing downward so rapidly. The following day it will be observed that the roots have touched the surface and are already scribbling out a course. If the framework is held over one's head the lines of clear glass stand out prominently against the dead black, and the fascination of watching the roots writing out their life history will amply repay for any trouble which may have been expended on the preparations. Some of the prettiest formations are those in which the radicles are abundantly supplied with roots' hairs, a good example of which is seen in the case of the cress pattern.

Of course the roots may be permitted to write for a longer or shorter period, and it is a matter which varies with each kind as to how long the process should be allowed to proceed. Eventually, if the tracings are permitted to go on indefinitely, the radicles become so elongated that other portions besides the tip commence to touch the smoked surface, and in this way the record is spoiled. In removing the glass great care is required, and at this stage it will be an advantage if the sheet has been supported by strips of wood, as mentioned earlier. If this is the case, by sliding the pieces of wood out, the glass drops away without the least fear of the roots being dragged across the smoky surface. The sheets of smoked glass are so easily damaged that most people will probably be glad to preserve the record of the seedlings' roots in a more permanent form. The illustrations accompanying the present article were prepared in order to give the true effect of their appearance, but a much simpler method is that of printing directly from the glass, which has been used during the experiments. The plates may be used as negatives, the smoked side being turned outward in the frame, and the sensitive printing-out paper being placed next to the plain surface of the glass. Of course the result will be that the tracings of the roots will be in black, but this does not in any way affect the value and interest of the records.

While it is impossible to go very deeply into this interesting behavior on the part of the roots of seedlings within the limits of the present article, there is little doubt that it must play a very useful part in the life of the plant. One of the greatest dangers to the extending root is that of meeting some obstacle in its course which it is unable to penetrate. Now if all radicles were to go downward in a straight line, it is quite clear that the risk of coming to a dead stop would be considerable. On the other hand, the constant moving about from one side to another results in a continual change of position, so that if a stone or some such obstacle should stand in the way of the course, the tip of the root is speedily carried to an altered position. Even after the most careful observation of the root habits of seedlings, it is impossible to say how far these movements are habitual and how far they are controlled by actual environment. Indeed, in many cases it is difficult to avoid the conclusion that the underground organs of plants are gifted with special senses of which we have little or no understanding.

New Work in Spectrum Analysis

By John W. N. Sullivan

THE method of spectrum analysis is based upon the well-known discovery of Sir Isaac Newton, that ordinary white light, on being passed through a prism, is split up into light of different colors. If, after the light has passed through the prism, it be projected upon a screen, we find a series of colors ranging from red at one end to violet at the other. Such a series, obtained in this way, is called a spectrum. Instead of a prism, it is more satisfactory, for many reasons, to use what is known as a diffraction grating, which consists of a piece of metal or glass ruled with fine lines very close together, there being usually 10,000 to 20,000 of these lines per inch. A diffraction grating splits up composite light into its constituent colors, and does so in a uniform manner; whereas different prisms decompose light differently, a fact which renders prisms less suitable than diffraction gratings for scientific work.

The spectra produced by different sources of light differ enormously from one another, a fact which renders spectrum analysis possible.

Before considering some of the recent achievements in the domain of spectrum analysis, it will be convenient to adopt a broad classification which will include all spectra.

The spectra of light emitted from various sources and passing direct to the analysing apparatus are called emission spectra and may be divided into three classes:

Continuous Spectra, where we have merely a sequence of colors ranging from red to violet.

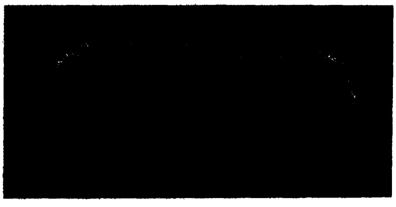
Line Spectra, where colored lines are found in their appropriate portions of the spectrum—for instance, a vivid green in the green region of the spectrum.

Band Spectra, where bands, sometimes of considerable width, take the place of lines in the spectrum.

In many cases bands may be split up into a number of lines packed very closely together by employing higher resolving power, but it is not certain that all bands may be split up in this way. The bands are usually more brilliantly illuminated at the edge nearest the violet end of the spectrum, although this is by no means an invariable rule. If now, instead of allowing the light to pass direct to the analyzing apparatus, we pass it through a gas or vapor at a lower temperature than the source of light, we get a different type of spectra, called absorption spectra. These spectra are characterised by having dark rays or bands on a bright background. The dark lines in the absorption spectrum correspond to bright lines emitted by the absorbing medium when in a state of incandescence.

If the light of the sun be examined by sufficiently high resolving power, it is found that its spectrum contains multitudes of fine dark lines, indicating the presence of absorbing gases in the sun's atmosphere. The exact positions of these lines in the spectrum are very carefully noted, and experiments are made to determine which gases have bright lines in corresponding parts of their emission spectra. In this way it is possible to identify the gases forming the atmosphere of the sun.

Corresponding to each line in the spectrum is a definite wave-length. If now the observer and the source of light are approaching one another, the wave-lengths appear shortened and the spectrum lines are shifted toward the violet end of the spectrum, where the wave-lengths are shortest. If, on the other hand, the observer and the source of light are receding from one another, the wave-lengths appear lengthened, and the spectrum lines shift toward the red end of the spectrum. From measurements of the amount of shift, the relative velocity of light source and observer may be calculated. It is in this way that the radial velocities of many stars have been measured.



The growing seeds in position, with the root tracing a course on the smoked glass.

Mammellicæ centricirrhha.

It is well known in our day that the visible spectrum is not the entire spectrum. Extending past the limits of visibility at the violet end of the spectrum, we come to the ultra-violet rays, whose presence may be detected by their action on a photographic plate. At the other end of the spectrum, extending below the red rays, we reach the region of the infra-red, which passes gradually into the region of the heat rays. The presence of the infra-red rays may be detected by their heat effects. Taking longer and longer rays, we reach, finally, the long electromagnetic waves, and in the other direction, far beyond the violet, it is now considered very probable that we reach those excessively short rays known as X-rays.

As an indication of the magnitudes involved, we may mention that the solar spectrum has been mapped out from wave-lengths 53,000 Angstrom units in the infra-red to 2,976 Angstrom units in the ultra-violet. An Angstrom unit is one ten-millionth part of a millimeter.

The wave-lengths of visible light lie between 4 by 10^{-5} centimeters and 7 by 10^{-5} centimeters. In the ultra-violet region waves as short as 1 by 10^{-5} centimeters have been discovered by Schumann, but in a paper published in 1912 by Friedrich, Knipping, and Lane phenomena are described which can only be due to waves of a length of about one hundred millionth of a millimeter, a length which is small compared to the radius of an atom!

A remarkable set of phenomena are comprised under the name *fluorescence*. It often happens that when light falls upon a substance, the substance emits light of a different color to the exciting light. This phenomenon is known as fluorescence and has been the subject of much recent work. Fluorescence is most markedly produced by the very refrangible rays, blue, violet, and ultra-violet.

In this connection Stokes enunciated the following law: The radiations emitted by a fluorescent substance possess greater wave-lengths and are less refrangible than those of the exciting light. It was at first believed that this law held good universally, but it was shown by Nichols and Merritt in 1904, in their researches on the spectra of fluorescent light, that in many cases this is not obeyed.

The fluorescence of bodies in the gaseous state was first observed by Lommel in his studies on iodine vapor, and later a whole series of fluorescent vapors have been discovered.

Some very remarkable work on the fluorescent spectra of sodium and iodine has been done by R. W. Wood. The spectra obtained by exciting sodium vapor or iodine vapor by light of a small range of wave-lengths (monochromatic light) he calls resonance spectra. It would appear that light of a certain wave-length falling on the systems of electrons which constitute the atoms of the vapor set up vibrations of the same, or approximately the same frequency, producing corresponding lines in the spectrum, that we have, in fact, a case of resonance. There would appear to be a strong connection between the bright resonance lines of these vapors and the dark lines of their absorption spectra. In all Prof. Wood's earlier work, he was of the opinion that each bright resonance line was in coincidence with some one of the numerous dark absorption lines, but in his last paper (*Phil. Mag.*, November, 1913) he finds that this is not the case. There can be no doubt that further study of these spectra will throw much light upon the intimate structure of the atom.

Spectrum analysis is thus seen to have a wide range. It is our only means of obtaining information as to the physical constitution of the heavenly bodies, and at the other end of the scale, it teaches us a great deal about the constitution of the smallest bodies in the universe.

The Disappearance of Gustav Hamel

EARLY in the morning of Saturday, May 23d, the well-known English aviator, Gustav Hamel, left Villacoublay, France, for Hendon, England. He was last identified at 12:15 P. M., when he left Hardelot, near Boulogne, on his way to Hendon, but a monoplane supposed to have been his was seen high in the air above Boulogne at 12:30 P. M. Wireless messages were sent to all ships in the Channel to watch for the aviator, but none of them has made a report of having seen the machine. Hamel recently announced that he would attempt to fly across the Atlantic for the Harmsworth prize. He was the first to repeat the upside down performances of Pegoud. His fate recalls that of Cecil S. Grace, who crossed the English Channel from England to France in December, 1910, and who disappeared on a return flight on December 22d.

A New Record for Dirigibles

THE new navy Zeppelin "L 3" recently stayed aloft for thirty-four hours, during a voyage from Friedrichshafen to Potsdam. An average speed of nearly 60 miles an hour is said to have been attained. While over Heligoland the "L 3" was in communication by wireless with dirigible "LZ 24," which was over Friedrichshafen.

Powerful Wireless Outfit for the Army.—According to the *Army and Navy Journal*, should an advance be made on Mexico, great reliance will be placed upon a strong force of cavalry assisted by aviators and an unusually powerful wireless outfit. A test was made by the Signal Corps at Washington of a wireless outfit mounted on a heavy automobile truck, which has an estimated range of 200 miles. If this range is realized, the Army will be in touch with the base at Vera Cruz until it reaches the gates of Mexico City.

Ancient Footwear Found in London

THE ancient shoes and sandals, pictured in the accompanying engraving, are not replicas, but the actual footwear of men who once trod the streets of London. They were dug up within the city limits and are on exhibition at the city museum. The two sandals shown date back to the days of the Romans. They were found in the peaty deposit of the Moorgate Street district They have been set up on plaster feet. On the left are two Saxon shoes. The one at the top resembles the Scottish and Irish brogue used at the present day in the Shetland Isles. It was discovered in London Wall. The shoe directly below it, with the iron stirrup, was found in the Ditch, Newgate. The shoe with long-pointed toe, at the bottom of the engraving, belongs to the early fifteenth century. The iron stirrup was found in Westminster, while the spur was dug up in Thames Street

It was during the reign of Richard III that this odd shoe, or "poulaine," was in fashion To keep the long toes of these shoes in shape, they were stuffed with moss

Measuring Moisture at a Distance

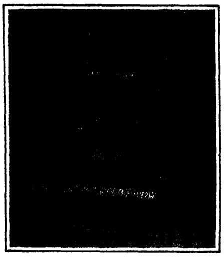
IN granaries, breweries, malt houses, spinning mills, gunpowder and explosive factories, grain houses, etc., great importance attaches to the amount of water vapor present in the air, and it is necessary that the amount of moisture present in the air should be capable of determination at any time with the minimum of trouble

One of the difficulties in this connection is the fact that many of the positions in which the atmospheric conditions have to be determined are not suitable for accurate observation, and hence the Constanz Schmitz system of hygrometers suitable for measurement at a distance. The Schmitz hygrometer is based on the principle of the well-known aspiration hygrometers Thermometers of a special type are used, consisting of a resistance coil of pure platinum wire, wound in a spiral form, on a central quartz tube, which is then inserted into a closely fitting outer protecting tube of the same material The whole arrangement is fused together, so that the platinum spiral is hermetically sealed, while any risk of the short-circuiting of adjacent turns is completely eliminated. The resistance of the spiral is accurately adjusted to a definite value. Two of these quartz glass resistance thermometers are mounted in an oblong case which is fixed in the room whose hygrometric condition is to be controlled; the accompanying drawing shows the arrangement One of the thermometers *A* is covered with a porous tube which is partly immersed in distilled water contained in a tray *C*, which serves to keep the thermometer wet. The second resistance thermometer *B*, separated from the thermometer *A* by a diaphragm *D*, is the so-called dry-bulb thermometer The air whose hygrometric condition is to be determined, passes through the oblong case and causes evaporation to take place on the surface of the wet-bulb thermometer *A*, with the result that heat is extracted from it in this way. A difference in temperature between the wet-bulb thermometer *A* and the dry-bulb thermometer *B* is set up. If the air were saturated with moisture, no evaporation would occur, and in this case the temperature of the two thermometers would be identical On the other hand, if the air were very dry, rapid evaporation would take place on the surface of the wet-bulb thermometer *A* and its temperature would be reduced, causing a considerable difference in temperature between the two thermometers The relation between this difference in temperature and the humidity at various temperatures has been determined scientifically A ventilator fan provides the proper velocity of air past the thermometers. The fan motor is switched on and off simultaneously with the thermometers. A central temperature indicator is mounted on a switch-board, to the back of which are fixed the necessary resistance coils and connections. Below the indicator are the push-buttons, by means of which any one of the distance hygrometers may be connected to the indicator. There is also a variable resistance to eliminate any error due to slight variations in the voltage of the battery by adjusting the resistance, while a test key is depressed until the indicator pointer shows exactly full-scale deflection. The push-buttons are interlocked, so that it is impossible to connect more than one thermometer with the indicator at the same time. When a button is pressed down, it remains down until a second button is depressed, when it automatically returns to "off" position.

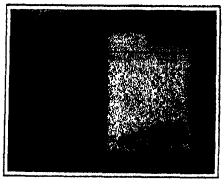
One button is provided as a releasing key, for use when it is desired to disconnect a point without connecting another in its place.

To take a reading, the push-buttons for the wet and dry-bulb thermometers are depressed, one after the other, and the temperatures are read off on the scale. By using a suitable conversion table, the readings can then be translated into measures of relative humidity. The instruments are of the Siemens type and have been produced in England.

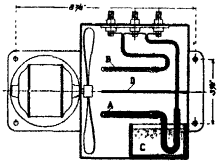
Bottom lowered to provide access to the water tray.



Casing removed to show the thermometers.



Hygrometer in normal closed position.



Sectional view of the hygrometer.

Aeroplanes and Gyrostat Control

A DEMONSTRATION of gyrostatic action was given recently before the Physical Society meeting in the Imperial College of Science, by Dr. G. Gray, of the Department of Natural Philosophy at the University of Glasgow. Dr. Gray showed three distinct methods of producing stability in a gyroscope mounted on such a moving body as a torpedo or an aeroplane. In the first method he mounted a gyroscope with two instabilities on a body supposed to be stable of itself. The construction and method of mounting was such that the stability of the gyroscope was derived directly or indirectly from the propeller forces. When the body was at rest the stability of the gyrostatic system was not complete; but, when the body was moving, even very slowly, the gyrostat was completely stable, and was then available for steering the body.

A second form of gyrostatic control was shown applied to the production of gyrostatic [illegible] [illegible]. When the machine tended to tilt to the left, as seen by an observer viewing it from behind and above, the front wheel was turned to the right of the observer (instead of to the left as in the ordinary machine) and the bicycle was righted by gyrostatic action. This device was said to be available for torpedoes and small aeroplanes.

A method of connecting up the gyrostat to the steering mechanism was described, a very small couple applied by the gyrostat resulting in the application of a very large couple to a vertical rudder at the stern of the torpedo, the couple being applied by means of a geared motor. A third kind of motor-car was shown, consisting of a front part and an *after* part, the two being connected by means of a vertical hinge The first part carried a gyrostat and the after part the propelling mechanism. The back portion applied a simple pushing force to the front portion. This system, which would appear on the face of it absurd to the ordinary observer, was completely stable when the gyrostat was spinning and the model was moving forward. The gyrostat detected any tendency to tilt, and obtained from the propeller the forces and momentum requisite to produce stability.

The lecturer also illustrated the application of gyrostatic action to the manipulation of the aeroplane. He proposed to fit an aeroplane with a gyrostatic nose, which would be available forcibly to maneuver the aeroplane. He explained that it would be fairly easy to construct such an aeroplane on a small scale. Elaborate experiments, however, would be necessary, and these were not possible for a private individual. Brought to perfection, such an aeroplane would be invaluable for reconnoitering purposes. It would possess stability in the air, which present-day aeroplanes certainly do not have. It could, as it were, turn on a pivot, and could be raised and lowered in the air by means of forces derived directly from the propellers.

Safer Night Driving for Chauffeurs

SO perfect is the headlight of to-day, that it affords remarkable safety in illuminating the roadway so far ahead as to give more than sufficient time to bring the car to a stop in front of any obstacle. But this very strength of automobile headlights is the thing that has created the second problem. Powerful light ahead, while diminishing the risk of accident for one driver, only increases the danger for a driver coming in an opposite direction. Every motorist knows how he is practically blinded when the glaring headlights of an approaching automobile strike him like a blow in the face. A sensible solution of the problem is the two-color goggle. This solution does *not necessitate* a weakening of the headlights, or prohibition of their use, or in any sense deprive the driver of the safety afforded by these strong headlights. This goggle has all the features of the ordinary goggle for day driving, with the additional feature of an extra segment in the top of each lens. The main and lower section of the glass is of light amber, and the vision is through this portion for ordinary driving. Above this, in the top of the lens, however, is a smaller segment of darker amber, and when the driver is confronted by dazzling headlights at night, he simply tips his head, to bring vision through this dark segment, which so reduces the glare that the approaching machine and roadway can be seen with perfect clearness. While this extra dark segment was added particularly for strong headlights at night, it has also proven to be a great advantage when driving along seashore, sand, or ordinary roads in the glare of bright sunshine. This dark segment then acts as a shade, or "cap visor," affording protection from the very strong daylight.

French Mistletoe in England

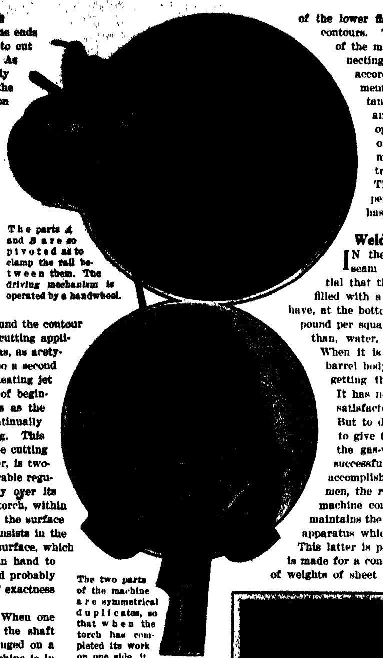
ALTHOUGH mistletoe grows in England, the bulk of that used for Christmas decorations in that country comes from the apple orchards of Normandy. In 1912 the London and South-Western Railway alone handled 1,500,000 bunches, weighing 650 tons and worth $300,000.

Cutting Street Car Rails With Gas

On account of the excessive wear-and-tear on the ends of street car rails, it is frequently advisable to cut away short sections and make replacements. As these rails, especially within city limits, are largely buried beneath the surface, it is desirable to do the cutting with the rails in place. A recent invention permits this service to be performed in an economic and excellent manner. The invention is a portable piece of apparatus, which may be put in place by one man. There are two parts *A* and *B* pivoted above, which may be made to clasp the rail between them, somewhat after the manner of a pair of tongs. These parts have, each of them, a driving mechanism adapted to turn the torch *C* through a large arc in such way that the nozzle will follow the contour of the rail. The driving mechanism is operated by a handwheel above. The two parts of the machine are symmetrical duplicates, so that when the torch has completed its work on one side, it may be detached and put in position on the other part, where it may be driven around the contour of the other side of the rail. The torch is a gas-cutting appliance. That is, it delivers a heating jet of a fuel gas, as acetylene or hydrogen, mixed into oxygen. There is also a second jet of oxygen, which is turned on as soon as the heating jet has sufficiently heated up the work at the point of beginning. The cutting then commences and continues as the compound torch moves around. The heating continually goes on just a little ahead of the actual cutting. This work could be done by hand operation of a suitable cutting torch. The advantage of using a machine, however, is twofold. In the first place, there is gained a very desirable regularity of movement; the torch is carried steadily over its path. Besides, the mechanical method holds the torch, within very close limits, to a predetermined distance from the surface of the work. The second part of the advantage consists in the control of the torch in positions at and below the surface, which would be difficult, if not dangerous, for the human hand to take. Hand operation of a rail-cutting torch would probably result in great waste of gas because of the want of exactness in handling.

The mode of operation is, briefly, as follows: When one of the handwheels is turned, a bevel pinion on the shaft carrying the wheel drives another bevel gear arranged on a second shaft. These two shafts are, when the machine is in place, both in one horizontal plane. One is perpendicular, however, to the other. The second shaft carries a worm which engages a wormwheel arranged on a shaft oblique to the horizontal plane. This third shaft runs down into one of the clover-leaf cases seen in the photographs. By a system of bevel and spur gearing, this third shaft transmits its drive alternately to a shaft perpendicular to the surface of the paper, on which shaft the torch is secured. The entire drive from the handwheel to the shaft for the torch provides for just two principal things: (1) reduction in rotary speed, and (2) rotary operation of the shaft holding the torch.

The torch is secured to its shaft by means of a slide lying in a vertical plane transverse to the web of the rail. At one end of this slide is the torch; at the other, a roller or traveler in contact with a cam track. While the turning movement is being accomplished, the roller rolls against the cam track, the result being that the nozzle of the torch follows accurately the contour of the rail, beginning, say, beneath the outer edge of the upper flange, then working in toward the web, then turning to follow the fillet between flange and web, then working down the web to the lower fillet, around it and out to the outer edge of the lower flange. Different cam tracks provide for different contours. The oblique shaft belonging to the opposite half of the machine is driven by a bevel-gear arrangement connecting the two oblique shafts. The two oblique shafts accordingly turn in opposite directions. The arrangements are such that if two torches be secured simultaneously in place, both will move downward together and upward together. Such a machine may be operated by a comparatively unskilled workman, once the proper adjustments have been made. It may be moved from point to point on a small hand truck, together with the tubes containing the gases. The amount of earth that has to be removed to permit of operation is small in amount. Only a little has to be taken out beneath the rail.



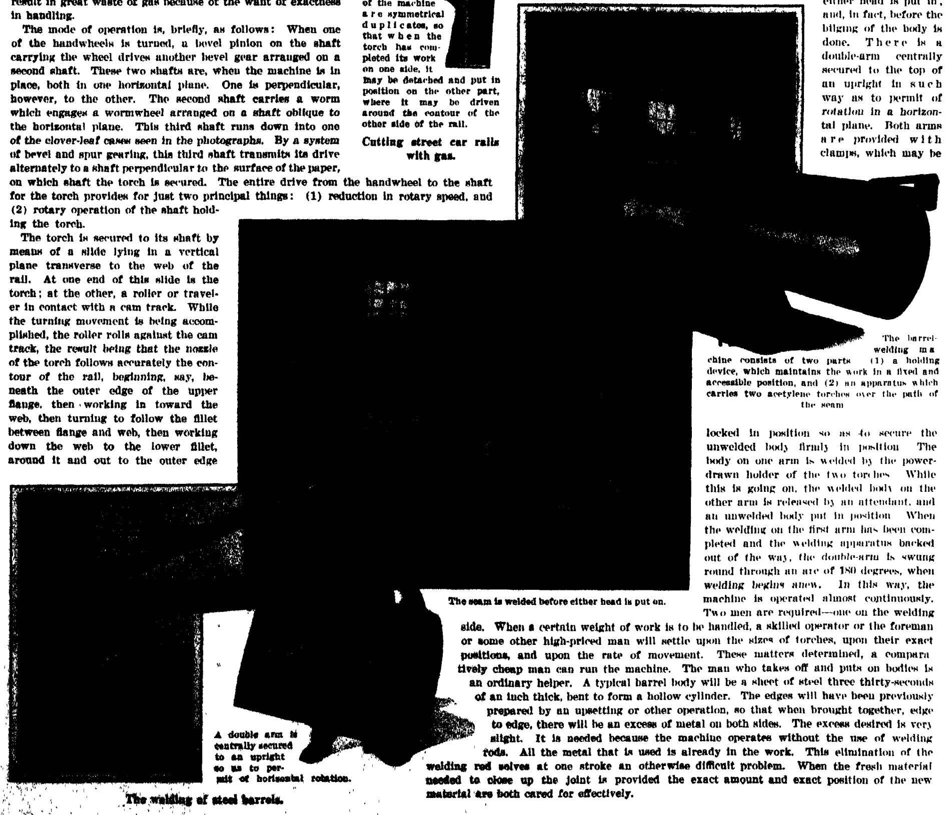
The parts *A* and *B* are so pivoted as to clamp the rail between them. The driving mechanism is operated by a handwheel.

The two parts of the machine are symmetrical duplicates, so that when the torch has completed its work on one side, it may be detached and put in position on the other part, where it may be driven around the contour of the other side of the rail.

Cutting street car rails with gas.

Welding Steel Barrels With Oxy-acetylene Torch

In the manufacture of steel barrels, the longitudinal seam constitutes a principal problem It is very essential that this seam be one not subject to leakage A barrel filled with a liquid of the same specific gravity as water will have, at the bottom of the seam, an internal pressure of about one pound per square inch. If the liquid is as fluid as, or more fluid than, water, there will be a considerable tendency to leak. When it is borne in mind that it is desirable to bilge the barrel body after the seam has been made, the difficulty of getting the best results will become still more apparent. It has now been found that a gas-welded seam will prove satisfactory, if sufficient care is exercised in making it. But to depend upon the skill of the welding operator and to give the time necessary for hand operation would make the gas-welding solution of the problem only moderately successful. Accordingly, a machine has been devised which accomplishes in half the time, with comparatively unskilled men, the results of highly skilled labor The barrel-welding machine consists of two parts: (1) a holding device which maintains the work in a fixed and accessible position; and (2) an apparatus which carries two torches over the path of the seam This latter is power drawn. By suitable arrangements, provision is made for a considerable range of speed, thus permitting a variety of weights of sheet metal to be handled. The seam is welded before either head is put in, and, in fact, before the bilging of the body is done. There is a double-arm centrally secured to the top of an upright in such way as to permit of rotation in a horizontal plane. Both arms are provided with clamps, which may be locked in position so as to secure the unwelded body firmly in position The body on one arm is welded by the power-drawn holder of the two torches While this is going on, the welded body on the other arm is released by an attendant, and an unwelded body put in position When the welding on the first arm has been completed and the welding apparatus backed out of the way, the double-arm is swung round through an arc of 180 degrees, when welding begins anew. In this way, the machine is operated almost continuously. Two men are required—one on the welding side. When a certain weight of work is to be handled, a skilled operator or the foreman or some other high-priced man will settle upon the sizes of torches, upon their exact positions, and upon the rate of movement. These matters determined, a comparatively cheap man can run the machine. The man who takes off and puts on bodies is an ordinary helper. A typical barrel body will be a sheet of steel three thirty-seconds of an inch thick, bent to form a hollow cylinder. The edges will have been previously prepared by an upsetting or other operation, so that when brought together, edge to edge, there will be an excess of metal on both sides. The excess desired is very slight. It is needed because the machine operates without the use of welding rods. All the metal that is used is already in the work. This elimination of the welding rod solves at one stroke an otherwise difficult problem. When the fresh material needed to close up the joint is provided the exact amount and exact position of the new material are both cared for effectively.



The barrel-welding machine consists of two parts (1) a holding device, which maintains the work in a fixed and accessible position, and (2) an apparatus which carries two acetylene torches over the path of the seam

The seam is welded before either head is put on.

A double arm is centrally secured to an upright so as to permit of horizontal rotation.

The welding of steel barrels.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

GARMENT HANGER.—A. BUCHWALD, care of Isidor Frank, 1673 Madison Ave, New York This hanger consists of a cardboard blank bent to form a head and chest with a hook projecting from the head The bent chest portion of the hanger holds the chest portion of the garment out in normal position, while the head of the hanger indicates the proportion and style of the garment, relatively to the bust of a normal person.

Electrical Devices.

CONNECTING CLIPS FOR ELECTRICAL CONDUCTORS J G ELKIN, care of Manhattan Motor Co, 68-72 E 131st St New York The clip here illustrated may be securely fastened to insulating conductor wire, enabling it to be quickly and conveniently attached to or detached from a binding post or the like It consists of a pair of spring pressed jaws pivotally connected and a clamp on the pivots of the jaws, adapted to engage the bare end of the wire conductor together with means for closing or opening this clamp

CONNECTING CLIPS FOR ELECTRICAL CONDUCTORS

TELEGRAPH RECEIVER—A PARODI, 38 Macdougall St, New York The invention relates to telegraph receivers producing a record adapted to actuate mechanism whereby messages may be received through the sensations of hearing and sight The primary object of the invention is the provision of a telegraph receiver adapted to record messages on a continuous tape, the construction being characterized by a new and improved means for feeding the tape

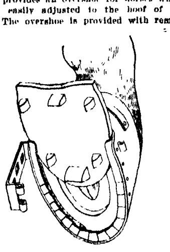
Of Interest to Farmers.

GATE OPENING MEANS—H SOMERS, Armstrong, British Columbia, Canada The invention relates to operating means for road gates, designed to be operated by a driver or equestrian, to open the gate and then to close the gate after having passed through The mechanism is such that it may be operated from either side to cause the gate to open away from the operator

PULVERIZER—J C MIRE, Dreyfus, La Mr Mire's invention consists of a pulverizer especially adapted for pulverizing the soil in the furrow It is designed to be attached to a turning plow to pulverize the soil as it is turned It comprises a bar having laterally extending arc shaped teeth, which gradually increase in size from one end of the bar toward the other

Of General Interest.

OVERSHOE FOR HORSES—MABEL BLACKMAN, 204 West 82nd St, New York The invention provides an overshoe for horses which may be easily adjusted to the hoof of the horse The overshoe is provided with removable soles formed with calks arranged to prevent slipping. The calks may be made of a material that will not injure pavements and yet will furnish a good footing under all conditions

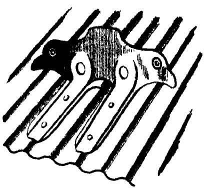


OVERSHOE FOR HORSES

ANTI-FREEZING OUTLET VALVE FOR TANK—J W WHIPP, care of L D Ratcliff, Decatur, Texas. In cold weather much difficulty is experienced with the outlets of tanks and the like which are apt to become frozen This is obviated in the present invention by providing an air space about the valve stem so that no water comes into contact with the stem or rod at the level of the water in the tank.

VENTILATING SHOE OR SLIPPER TREE—W. A. NICKLESS, care A. Steinhardt & Bro, 860 Broadway, New York, N Y. In order to ventilate the shoe or slipper thoroughly and prevent undue shrinking of the leather this tree is made with a toe or a vamp form having longitudinal passages beginning at the back of the form and extending forwardly and vertical passages intersecting the longitudinal ones and extending from the bottom of the form to the arched top thereof.

SNOW GUARD FOR ROOFS.—A. DANNER, Hagerstown, Md. The snow guard consists of a plate metal piece rolled to the form shown in the illustration. It may readily be attached to a roof Preferably it is used alone, but if desired a bar or board may be secured to the upper side of the plate by means of screws inserted through the holes in the plate.



SNOW GUARD FOR ROOFS.

Heating and Lighting.

ATTACHMENT FOR GAS METERS.—J. G. HAYDEN, New Lexington, Ohio In order to remedy the offset caused by shrinkage or expansion of the diaphragms in meters which depend on the pull of a diaphragm to operate a planetary valve controlling the passage of gas through the meter, the present invention provides an adjustment of the valve operating mechanism to compensate for the variable amplitude of swing of the actuating diaphragm.

PROCESS FOR PRODUCING COMPRESSED AIR OR COMPRESSED GAS ESPECIALLY FOR OPERATING OF LAMPS—W. LIEDKE, 17 Grolemannstrasse, Berlin-Charlottenburg, Germany This process of compressing air or gas for feeding lamps consists in vaporizing quicksilver, ejecting the vaporized quicksilver into a body of air or gas to force the latter along with the vapor into a reservoir to compress the same therein, and conducting the compressed air or gas to the lamp.

Household Utilities.

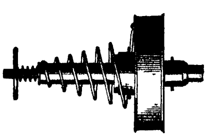
TRAY.—M. B. SOLOMON, care of American Tray Co., 233 Mercer St., New York, N. Y The purpose of the inventor is to provide a tray arranged to permit of conveniently assembling the tray, bottom, frame and railing and fastening the same together without resorting to soldering, at the same time forming an exceedingly strong tray which is also neat and ornamental

DRIP WATER SAFE—J. J. HICKEY, 2130 Lexington Avenue, New York, N. Y The invention relates to sanitary engineering and has particular reference to improvements in plumbing apparatus associated particularly with iceboxes, refrigerators or the like. It provides a very simple drip water reservoir or safe for refrigerators which may readily be applied to or removed from the main waste pipe without the use of tools

CREASING IRON—H W POGUE, 1745 North Church St, Decatur, Ill The invention relates to irons for creasing trousers, coats and other garments and provides the iron with opposed members between which the portion of the garment to be creased is received, the members being provided with guiding runners to assist the user in guiding the iron

Machines and Mechanical Devices.

TRANSMISSION DEVICE.—J. W. HOWSEY, Darlington, Wis The invention provides a transmission device with an interposed spring, affording a cushion between the driving pulley and the shaft actuated thereby It is particularly useful in driving cream separators or dynamos requiring very steady speed and may be employed with an internal combustion engine, to absorb the shock due to the periodic explosion



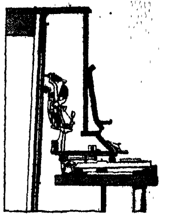
SHOCK-ABSORBING PULLEY.

SAW SHARPENER.—P. HILSINGER, Killawog, New York The inventor aims to improve the construction of saw sharpeners and increase their efficiency without unduly complicating the mechanism employed With the improved device the handling of the saw is greatly facilitated and the placing of the saw teeth for the purpose of operating upon them is rendered specially accurate.

FIBER SEPARATING MACHINE.—M. E. PARKS, Box 541, El Paso, Texas. The invention relates particularly to a machine in which the separating element travels faster than the feed crushing roll, but slower than the drawing roll, so that the butt end of the plant stock can be effectively acted upon by the separating element, there being coacting [illegible] devices which carry tools to remove the bark, pulp or other matters from the fiber.

Musical Instruments.

TRANSPOSING DEVICE.—J. VACCARO, deceased; PIETRO VACCARO, administrator, 79 Franklin St., Bristol, R. I. In order to permit of playing a piece on the piano a half tone, whole tone, or several tones higher or lower than the one to which the piano is ordinarily tuned, a shiftable connection is interposed between the keys and the abstract of the piano action. A locking device is provided for engaging the rear ends of the keys to hold them in lowermost position, and the operating means for this locking device forms a locking device for the shiftable connection.

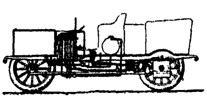


TRANSPOSING MECHANISM FOR PIANOS.

Prime Movers and Their Accessories.

CARBURETER.—L. R. MILLER, JR., Dodge City, Kansas. Mr. Miller has for his object in this invention to provide an improved carbureter having a movable mixing tube, so shaped and moved that it acts as a throttle and is connected to the usual throttle operating mechanism and is operated in the same manner as the throttle is operated.

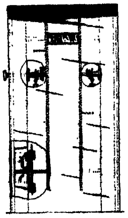
VEHICLE POWER PLANT.—E. F. HOWE, El Centro, California To provide a simple transmission between the motive power generator and the wheels of an automobile, Mr Howe has invented a vehicle power plant, generating and using compressed fluid, which does not require a large number of mechanical elements for its transmission. The plant comprises a rotary explosive engine, a fluid compressor and a reversible fluid motor for propelling the vehicle



POWER PLANT AND TRANSMISSION FOR AUTOMOBILES.

Railways and Their Accessories.

STREET INDICATOR FOR CARS.—F. H. WEBSTER, Marvell, Ark. The invention provides a street indicator in which the names of successive streets are printed upon a band which is moved by a step by step mechanism. When a car passes a street, the name of which is not to be displayed, such name will be practically skipped, although it may be carried upon the band An automatic reversing mechanism comes into play when the car reaches the end of its route and starts upon its return trip.



STREET INDICATOR FOR CARS.

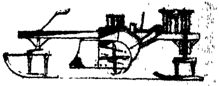
RAILWAY-SPIKE—L. WECHSLER and R. SCHERER, 19 West 118th St., N. Y. The shank of the spike is divided into a number of points adapted to be deflected outwardly and upwardly when forced into a railway tie. A spreading member is provided which is adapted to fit in a bored out socket in the tie so as to cause the points to be deflected with the least possible mutilation of the wood.

AUTOMATIC RAILWAY GATE.—H. GOSKLAR, 206 W. 151st St., New York, N. Y. Hydraulically operated gates for railroad crossings, adapted to be automatically closed before an approaching train and opened after the train has passed, [illegible] tion. The mechanism [illegible] inter-communicating cylinders [illegible] stern, the plunger of a larger cylinder [illegible] adapted to be engaged by a vehicle moving on the track, while the smaller cylinder is fitted with a plunger that operates the gate.

AUTOMATIC RAILWAY GATE.

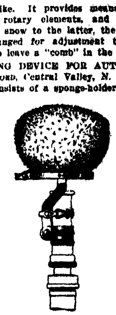
Vehicles and Their Accessories.

SNOW PLOW—W. L. BRADIG, St. Francis, Maine. This invention provides co-acting means for taking up the snow and causing it to be raised and deflected to the side of the road. It removes snow from highways, logging roads, and the like. It provides means associated with the rotary elements, and adapted to gather the snow to the latter, the said means being arranged for adjustment to the road level, or to leave a "comb" in the road center.



IMPROVED SNOW PLOW.

WASHING DEVICE FOR AUTOMOBILES.—H T. FORD, Central Valley, N. Y. The invention consists of a sponge-holder which may readily be applied to the nozzle of a hose, for washing an automobile, so that the sponge will be directly in line with the stream of water issuing from the nozzle, and may, when desired, be thrown out of this stream, to permit the stream to be played directly upon the parts to be wished.



WASHING DEVICE FOR AUTOMOBILES.

Designs.

DESIGN FOR A VEHICLE FRAME.—J. WORKSMAN, 30 S Main St., Asbury Park, N. J. The design covers a frame of rectangular form coupling two bicycle forks. The frame is attached to the heads of the forks, while there is a spacing member secured to the forks at their lower end, and diagonal bracing members running from the head to the center of the spacing member.

DESIGNS FOR TUMBLERS, GOBLETS, JUGS, OR SIMILAR ARTICLES.—W. E. HUNTER, care of Economy Tumbler Co., Morgantown, W Va. Mr. Hunter has obtained three patents on ornamental designs for tumblers, goblets, jugs, and the like. The designs consist of ornamental bands adapted to be run around the body of the vessel. One of the designs provides for a band of leaves interrupted at intervals by a conventional figure and a spray of flowers. A second design consists of a conventional chain or rope effect, under which there is a wavelike band. The third design consists of a band made up of conventional flowers in the form of scrolls, with a band of leaves above and a draped effect below.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

The Extra Value in the Industrial Motor Built by Westinghouse Electric

EXPERIENCED engineers will tell you that electrical equipment is one of the few things that cannot be purchased by appearance, inspection or even by testing.

It is especially important that manufacturers who are now ready to install electric motor drive on the machines in their factories know that the most important part of a Westinghouse electric motor is the part that cannot be "weighed"—the engineering ability that has been put into its design.

It is the thing that makes the Westinghouse Motor designed for some particular purpose do its work even better than human intelligence could direct it — that makes it economical of current — that gives it the ability to handle large overloads when necessary — that makes it always ready to start at any time and run as long as wanted — that makes it give good service for years in spite of hard knocks and rough treatment.

The Westinghouse Organization is probably unique in its engineering department. All the money in the world could hardly have brought these men together. There are certain ideals and standards of work in the Westinghouse Electric Organization that must appeal to the highest type of engineering mind. The Westinghouse engineers are known all over the world.

This extra brain-service goes with every piece of electrical apparatus that bears the name Westinghouse Electric. It aids in the selection of machines that are best suited for your particular business, Mr. Manufacturer. You do not have to stand the burden of experiment, for the Westinghouse Electric Organization has gathered the most complete written data on industrial electrical installations ever gotten together.

Before you even plan, talk to a Westinghouse Electric man.

YOU have seen this name on the telephone in your home and office, in hotels and other public places, and on cable reels along the streets and highways.

The universal use of these telephones and cable has given international prominence to their makers, the Western Electric Company.

In every Bell telephone—8,000,000 of them throughout the United States—you see the product of this company. Thousands more are used by other telephone companies and on private systems. Western Electric telephones are also standard on many of the foreign telephone lines.

But the scope of the Western Electric Company's activities goes even further.

The Western Electric Company furnishes equipment for every electrical need. Every article is protected by the prestige of the name and the guarantee of the maker.

Therefore, when you invest in a Western Electric vacuum cleaner, inter-phone, electric iron, toaster, warming pad, household motor, electric washing machine, or other Western Electric household helps, you may be assured that you have obtained the best procurable.

The booklet, "Western Electric Household Helps," describes all of these home utilities. A postal, asking for booklet No. 168-AG, will bring your copy.

WESTERN ELECTRIC COMPANY

Analytical Comparison of the Bird and Monoplane.

(Concluded from page 462.)

retained without employing the treacherous wire.

The control of the machine is very simple. The ascent is made by pushing downward and forward on the steering-wheel; the descent by pulling the wheel backward and upward. Steering from right to left is accomplished by turning the wheel from right to left, similarly to steering an automobile. Lateral balance is gained by operating a second wheel in conjunction with, or independent of, the steering-wheel.

The landing chassis is very simple, composed of two wheels and a skid. The wheels are mounted on V-shaped members and suspended on twin coil-springs, lying parallel with the body of the machine. After leaving the ground the wheels are folded upward and inward, disappearing through apertures in the body of the machine, which are closed by sliding doors. The wheels are folded by worm-gears operated by the feet of the aviator.

Three-bladed propellers are employed. The motor turns 1,000 revolutions per minute, while the propellers turn 750 revolutions per minute. Propellers are mounted on the entering edge of the main planes, five and one half feet from the sides of fuselage. This plan gives the tractile power at the points most needed.

The seat of the observation officer can be turned from side to side or raised or lowered, similar to a piano stool. This method of mounting the seat affords a wide scope of vision. The machine-gun of demountable form, which may be raised or lowered or turned from side to side, is mounted on the cowl, directly in front of the observation officer. Two port-holes are built in the bottom of the fuselage just below the pilot and observation officer. These openings afford a splendid view of the underlying country Bombs may be dropped, the machine-gun fired, and pictures taken through them. These port-holes can be closed with sliding steel doors when necessary, for protection from the enemy. The machine is fitted with regulation wireless outfit. The electricity is supplied by a generator and storage battery, which also supply the searchlights when flying at night. A small rain-vision wind-shield is fitted to the cowl just in front of the occupants, which gives good protection during high speed and stormy weather. Gas and oil tanks are mounted between the pilot and motor over the center of pressure, according to standard practice. Rubber rope or chain is used to transmit the power from the motor to the propellers. Generous sized air-cushions are used to upholster the seats and cock-pit of the fuselage. These will protect the aviator and passengers in case of a hard landing. All instruments that assist the aviator are placed directly inside the cowl in front of the pilot.

Weaving Real Persian Rugs

(Concluded from page 464)

a pile thread t is left dangling between the warp threads a, a^1 in front of the crossing a^2. The warp threads a, a^1 are now returned to normal position, as shown in Fig. 5, whereby the loose end of the pile thread t extends downwardly on the outside of the warp thread a, is looped over the warp thread a, passes between the warp thread a, a^1 and around the other warp thread a^1 to then extend upward on the outside of this warp thread a^1. The tuft yarn tube h is now again passed downward between the now parallel warp threads a, a^1, as shown in Fig. 6, to complete the Persian knot, and while the tuft yarn tube h is in this lowermost position, the pile thread is cut by a transversely moving knife k, after which the tuft yarn tube h rises to uppermost position. One, two, or more weft or binding threads l are now passed through the opened shed and the Persian knot and weft thread are beaten home by the lay.

The selection of the yarn tubes carrying the differently colored pile threads t is made by the overhead Jacquard mechanism, the perforate cards of which may

Sears, Roebuck and Co., Chicago

ONLY $15.00 FOR THIS 3/4 H.P. ENGINE

Height of engine 18 inches; weight of engine 45 lbs. Can be carried in a suit case.

Just the thing for running a lathe, drill, saw, ice cream freezer, washing machine, fan, sewing machine, auto air pump.

This engine fills a long felt want. No workshop is complete without power and no workshop can afford to be without power when the EMPIRE can be purchased for almost nothing. A child ten years old should learn to operate it in thirty minutes.

Description The EMPIRE is a two-cycle, jump spark engine. It is made along simple and practical lines so that it is not difficult to handle. The crank shaft is made of best drop forge steel. The piston has two rings, being also made of the best obtainable material. The water hopper is of ample capacity to keep the engine at the proper running temperature. The fuel is kept in the base of the engine and is mixed with the lubricating oil, this doing away with unnecessary sight-feed oilers, at the same time insuring proper lubrication. The speed is variable, from 300 to 1000 R. P. M., and can be changed while the engine is in motion. Engine shipped complete, including batteries, spark coil and all equipment necessary to operate

Guarantee We unconditionally guarantee that every pound of material used in the EMPIRE 3-4 H. P. is free from defect in material or workmanship, and will replace any time within three years from date of purchase any parts showing defect from either cause above stated

OUR PROPOSITION

We will ship one of these engines complete on receipt of $15.00, money order or bank draft, to any address, or will make a time proposition as follows $10.00 money order or bank draft with order, and $2.00 per month for five months or $20 in all.

This $15 price is special and holds good for a limited time only. Better order today. Exclusive agency given to live wires.

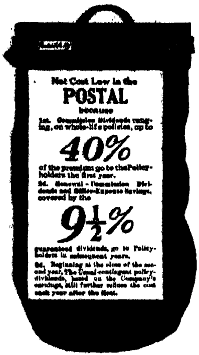
The wife works hard, too—in the home—and is equally interested with her husband in sound insurance-protection, such as that offered by

The Postal Life



Net Cost Low in the

POSTAL

because

1st. Commission Dividends ranging, on whole-life policies, up to

40%

of the premium go to the Policyholders the first year.

2d. Renewal-Commission Dividends and Office-Expense Savings, covered by the

9½%

guaranteed dividends, go to Policyholders in subsequent years.

3d. Beginning at the close of the second year, The Usual contingent policy-dividends, based on the Company's earnings, still further reduce the cost each year after the first.

The woman's interest in insurance-protection and health-conservation is not less than her husband's. Nowadays thoughtful people talk these things over together.

Why Not Investigate?

The Postal Life issues all the standard forms—Whole Life, Limited-Payment Life, Endowment, Joint-Life, Child's Welfare and Industrial—but it is probable that you will be interested most in a Monthly Income Policy—the Contract that will provide a regular monthly income for life.

Write the Company for Official Information, giving date of birth of both husband and wife, also occupation. The Company will send full particulars, and then you can talk it over together. *Please mention the SCIENTIFIC AMERICAN June 6.* No agent will be sent to visit you; the benefit of this commission goes to you because you deal direct.

POSTAL LIFE INSURANCE COMPANY

Water Without Pumping Plenty of It Too

ABSOLUTE reliability, low first cost, and no need of attention and repairs are the requisites of a perfect water system. Engines are often a source of annoyance, windmills depend entirely upon the wind, and hand pumping is enough to drive anyone off the farm. Be absolutely free from all water supply troubles—install a

RIFE RAM

Any stream in your neighborhood having a fall of three feet or more and a supply of three gallons or more per minute, will operate it. The Rife Rams vary in size from a machine for one family's use to a city water system. Thus you can co-operate with your neighbor if there is no stream on your farm. [illegible]—Low First Cost—No Repairs [illegible]—No Pumping—No Fuel—No Labor are the high qualities of the Rife Ram. No skilled labor required to install it. Over 11,000 in daily use. Satisfaction guaranteed. Write today for catalog and Tell Us Your Water Supply Conditions and we will send free estimate on your requirements. [illegible]

RIFE ENGINE COMPANY

[illegible]

be regarded as equivalents of the *talim* sheets used by the Oriental weavers. The loom is wholly automatic, and at each operation, as above described, a whole row of pile knots is made, corresponding in color to a predetermined design.

What a very industrious Oriental weaver can weave in about a year this loom accomplishes in a single day, and consequently the product made by this loom can be sold considerably cheaper than the hand-made product, considering the quality of the material as being alike.

The power loom shown in our illustration weaves a rug 10½ feet wide and of any length, according to the design. It was built by the Crompton and Knowles Loom Works, whose faith in the invention was largely instrumental in achieving success.

The importance of this invention of Mr. Dalkranian was early recognized by the late Mr. Nazar Costikyan, founder of the well-known firm of Oriental rug importers, Costikyan Bros. & Co., of New York city, and through Mr. Costikyan's financial assistance and that of his son, Mr. Mihran N. Costikyan, the inventor was enabled to reduce his invention to practice.

Summary of the Eighth Report of the Carnegie Foundation for the Advancement of Teaching.

THE eighth annual report of the president of the Carnegie Foundation for the Advancement of Teaching, shows a total endowment of $15,325,000, and an expenditure for the year ending September 30th, 1913, of $658,431. Of this $519,440 was distributed in retiring allowances to professors, and $80,949 in pensions to their widows, a total of $600,389. Thirty-three allowances were granted during the year, making the total in force 403, the average annual payment to an individual being $1,703. The total distribution from the beginning has been $2,936,927. The educational work of the Foundation was separately endowed in January, 1913, by a gift of $1,250,000 from Mr. Carnegie through the Carnegie Corporation of New York. This body, which is endowed with one hundred and twenty-five million dollars for "the advancement and diffusion of knowledge and understanding," has five *ex-officio* trustees, of whom one must always be the president of the Carnegie Foundation for the Advancement of Teaching.

In connection with the Foundation's work as a center of information concerning pensions, the president discusses pension systems that are maintained by half a dozen colleges, the development of new systems at Brown University, the Rockefeller Institute, and the American Museum of Natural History, the new federated pension system of the English universities, and the proposed system for the clergy of the Episcopal Church. Among pensions for public school teachers the report discusses the misfortunes of the New York city system, and commends the plans of the new State system in Massachusetts.

Much of the report is devoted to the development of the educational work of the Foundation into a separate Division of Educational Inquiry. Its recent work includes a study of education in Vermont at the request of the Vermont Educational Commission, of legal education at the request of a committee of the American Bar Association, and of engineering education at the request of a joint committee representing the national engineering societies.

The study of education in Vermont, already distributed, represents the first survey that has been made of a State's educational activities as a whole. The study of legal education has been begun by a first-hand inquiry into the bar examinations of every State, a special study of legal teaching by Prof. Josef Redlich, who came from Vienna for the purpose, and by a personal examination of each of the 160 law schools in the country. Plans for the study of engineering education are now being completed. The earlier educational work of the Foundation is continued in the report by commendation

The Many Uses of UNION CARBIDE *and* ACETYLENE

IN GRAY DRUMS WITH BLUE BANDS

The Union Carbide Company is the largest user of industrial horse-power in the world.

UNION CARBIDE is the granite-like material that yields acetylene gas. In the process of manufacture the power of Niagara Falls and the great rapids at Sault Ste. Marie is transformed into electric current, which in turn is changed into heat. This heat is used to maintain the highest temperature known to science in the hundreds of huge electric furnaces which turn out the Carbide.

The process of making Acetylene from Carbide is so simple it has brought this gas into world-wide use. Today tens of thousands of mine workers are wearing acetylene mine lamps on their caps—thousands of acetylene torches are illuminating big outdoor construction projects—tens of thousands of automobiles are equipped with acetylene headlights—thousands of factories and machine shops are using oxy-acetylene metal cutting and welding torches—thousands of acetylene lighthouse buoys illuminate our sea coast. Others light the whole course of the Panama Canal. And hundreds of thousands of country home families are using HOME MADE ACETYLENE for both lighting and cooking. The thousands of tons of UNION CARBIDE used to make this acetylene is purchased direct from the Union Carbide Company's warehouses located at shipping points all over the country. In the hundred pound drums in which it is packed UNION CARBIDE is as safe to ship, store and handle as coal. It won't burn and can't explode.

For information regarding any of the uses of Union Carbide address

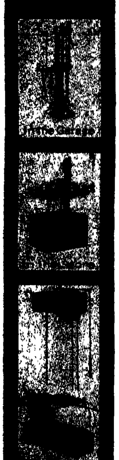
BOWSER Makes Oil and Gasolene Pay



How To Get The Utmost From Oils and Gasolene!

The S. F. Bowser Company has solved the problem for over a million users of 500 different Bowser Oil Storage Systems—from users of the simple equipment for the private garage to the master Storage, Circulating and Filtering Systems for giant power plants.

In these places, as well as in stores, dry cleaners' plants and *wherever else oil is used,* Bowser systems are keeping all oil products free from contamination and mishandling.

Every drop of gasolene and oil that comes in is conserved.

Every drop automatically measured as it goes out. Every drop recorded. Every drop *full strength.*

And with all this is utility, safety, convenience, economy of floor space and a new standard of efficiency—all *Bowser-compelled.*

BOWSER ESTABLISHED 1885

Safe Oil Storage Systems

In Garages Bowser systems keep gasolene *underground safe and sound.* No waste, evaporation, spillage, theft or loss of any kind. No power gone up in vapor. No danger from explosion. No oily floors. No careless handling. Keeps the "gas" in gasolene. Easily installed. Also portable units for the safe, efficient handling of gasolene and lubricating oils about the garage.

Stores and Factories In stores Bowser self-measuring equipment keeps kerosene and all oil products free from waste and danger, and away from other merchandise. None of the old-time discomfort, hazard and "guess work." In factories Bowser equipment—from Departmental Units to the Individual and Centralized Circulating and Filtering Systems—*compel* care, accuracy and economy in the *handling of all oils.* Oil can be used over and over. Save floor space. Keep oil off the floors. Keep men from visiting at the oil barrel. Make for added efficiency and economy every way.

Thirty Years Experience Yours

Let Bowser solve your problems of oil storage and utility. Use the coupon. No charge No obligation There is just the Bowser system for your very needs Easily installed, Cost small. Saving great Bowser equipment "keeps tab" on the precise use of whatever kind of oil you use, whether gasolene, paint oil, lubricants, etc. Send the coupon today.

of the present tendency of college entrance requirements toward both elevation and flexibility. The need for further improvement is shown by the fact that only 55 per cent of the students now in our colleges are high-school graduates. The decrease in the number of medical schools in the country from 162 in 1910 to 115 in 1913, and the rapid improvement of the better schools are commented upon with appreciation. A general study of the problems of the State regulation of higher education is illustrated by a detailed account of the recent crisis in educational affairs in Iowa.

The report further presents a study of the financial status of college teachers as compared with the situation presented in a similar study published five years ago. The ordinary salary of a full professor in the institutions associated with the Foundation is now $3,000. During the last five years the salaries of instructors have risen by about $80; those of junior professors show a gain of from $120 to $225; those of full professors show an increase from $125 to $350.

The report concludes with a frank criticism of contemporary college catalogues. It is accompanied by the annual report of the treasurer.

Alum in Foods

THE much-mooted question of the effects of aluminium compounds on the nutrition and health of man forms the subject of a recent report by the Referee Board of the U. S. Department of Agriculture, the substance of which is published as Bulletin No. 103 of that department. The conclusions of the board are supported by the results of three sets of extensive experiments on human subjects, conducted independently by Dr. Russell H. Chittenden, of the Sheffield Scientific School; Dr. Alonzo E. Taylor, of the University of Pennsylvania Medical School; and Dr John H. Long, of the Northwestern University Medical School, all of whom are members of the board. Although alum is used in making pickles, preparing maraschino cherries, etc., the amount that thus enters into human diet is very small compared with that consumed in baking powders; hence the attention of the board was directed chiefly to the effects of alum baking powders. It appears that "a saline cathartic residue results from the reaction of every known form of baking powder now commonly employed," and when such powders are used in large quantities—e. g., when a person subsists mainly on baking-powder biscuits, as may happen in camp life—the cathartic effect would be noticeable and ultimately injurious On the other hand, the amount of such powders used in an ordinary domestic diet is found to have no such effect, and does not in any way impair the nutritive value of foods. "In short, the board concludes that alum baking powders are no more harmful than any other baking powders, but that it is wise to be moderate in the use of foods that are leavened with baking powder."

A Remarkable Series of Synoptic Weather Charts, showing the meteorological conditions over the southern hemisphere south of latitude 30 S for each day from October 1st, 1901, to March 31st, 1904, has just been published by the Royal Society of London as a volume of the scientific results of the National Antarctic Expedition of 1901-04 The data on which these charts are based were gathered from vessels of all kinds, including exploring ships, as well as from the meteorological observatories and stations of the lands surrounding the Southern Ocean, and cover about one quarter of the earth's surface. No such charts have ever before been published for the southern hemisphere. Their preparation has been in progress for eight years at the Meteorological Office, in London, under the direction of Commander Campbell Hepworth, marine superintendent.

The War Department is reforesting a large area near Fort Bayard, New Mexico, for use as an army hospital site.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

NEW BOOKS, ETC.

On Old World Highways. A Book of Motor Rambles in France and Germany, and the Record of a Pilgrimage from Land's End to John o'Groats in Britain. By Thomas D. Murphy. Boston: L. C. Page & Co., 1914. 8vo.; 388 pp.; 16 color plates and 40 duogravures. Price, $3 net.

A most attractive travel book comes to us under the title "On Old World Highways." By far the larger portion of the book is devoted to Great Britain; here the author's treatment becomes most intimate and sympathetic, and we are given some very fine reproductions in color from such canvases as those of MacWhirter and Moran. The viewpoint is one that makes especial appeal to the motorist who is educated, or at least interested, in historic and picturesque values, but much practical suggestion as to roads, hotels, etc., is embodied in the text. There is a large outline map of France and Germany, and others of England and Scotland. The final chapter on "The English and Their Institutions" is sketchy and vigorous rather than profound, but it will serve to correct some prevailing impressions as well as to offer a word of warning to American motorists who have occasion to patronize wayside repair shops.

Hydraulics. A Text-Book for Students and Engineers. By Ernest H. Sprague, A.M. Inst. C.E. New York: D. Van Nostrand Company, 1914. 12mo.; 184 pp.; 89 illustrations. Price, $1 net.

Many of the accompanying diagrams are very crude, though not sufficiently so to be obscure. The text, compiled from standard treatises and lecture notes, is well arranged, and all important principles are ably covered. The author does not scruple to use the calculus wherever convenient; he even hopes that its inclusion may prove of advantage in familiarizing the student with its advantages and in removing the exaggerated fear which the tyro exhibits toward this most important instrument of analysis.

Echappements d'Horloges et de Montres. Exposé Technique, Descriptif et Historique, des Echappements d'Horlogerie. Paris: Bureau de l'*Almanach de l'Horlogerie-Bijouterie.* 8vo.; 263 pp.; illustrated. Price, francs, 4.

This latest volume from the press of Charles Gros is an exhaustive description, from both historical and technical points of view, of those delicate and ingenious mechanisms known as escapements. Every detail of the various types is shown in the 275 cuts that enrich the exposition. Inventors will find a study of the movements and combinations of distinct aid in their work.

Progressive Chemistry. Practical Experiments for Secondary Schools. Prepared by the Teachers of Chemistry in the High Schools of Minneapolis, Minn. Price, 35 cents.

The authors present their material in the form of a writing pad. The upper part of each page is devoted to instructions for carrying out the various simple experiments. The lower portion of the page is blank, for the equations and results of the student. The index shows some forty captions, including tests of water and milk, the determination of simple unknowns, litmus tests and neutralization.

The Fundamental Basis of Nutrition. By Graham Lusk. New Haven: Yale University Press, 1914. 12mo.; 62 pp. Price, 50 cents net.

Prof. Lusk's little book furnishes the clearest exposition we have seen of food values and their relation to the cost of living. The chief aim of the work seems to be to enable the family of small income to select the foods highest in nutriment at the lowest expense. The chapter on beri-beri is in the nature of a digression from this purpose, and it might have been well to have given in its stead a brief discussion of the correct principles of preparing food for the table. So much depends upon the conservation of certain elements, and the bringing out of flavor, that no book on nutrition is complete without some warning of the changes that poor cookery produces in the nutritive values of food.

Bau, Unterhaltung und Verteidigung der Flussdeiche. Von Ehlers, Geheimer Baurat, Professor an der Technischen Hochschule Danzig. Berlin: Wilhelm Ernst & Sohn, 1914. 8vo.; 54 pp.; illustrated. Price, 3.20 marks.

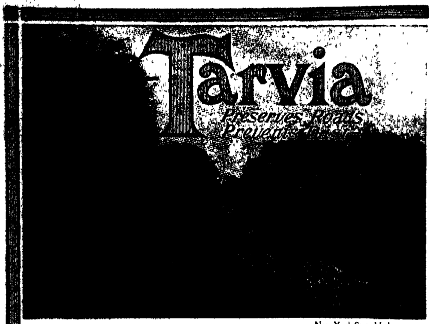
In bringing out this work, the publishers give us another authoritative and valuable discussion. Dikes, levees, and revetment work are made plain by a profusion of charts and diagrams. The control of river water is studied under varying aspects and conditions, and successful constructions are presented for the reader's consideration.

Forged Egyptian Antiquities. By T. G. Wakeling. London: Adam & Charles Black, 1912. Price, $2 net.

Mr. Wakeling's book makes entertaining reading, and will no doubt serve the purpose of placing amateur collectors on their guard. It does not attempt to give positive instructions as to the best manner of detecting frauds, but rather to present its information by citing examples of actual cases of fraud which have come to the author's attention.

India-Rubber Laboratory Practice. By W. A. Caspari, B.Sc., Ph.D., F.I.C. New York: The Macmillan Company, 1914. 12mo.; 196 pp.; illustrated. Price, $1.50 net.

This text is a compendium of practical analytical methods, every one of which has been used by the author, and is vouched for by him as pro-



New York State Highway,
Mapleton, N. Y.
Constructed with "Tarvia X"

Do dusty roads bother you?

DON'T you often find the fun of a ride or a walk through the country marred by the dust—aren't there days when you are fairly choked with the clouds raised by passing automobiles, your shoulders white with dust, your clothes all but ruined?

And haven't you seen that dust float over the lawns into fine homes, making the verandas uninhabitable and ruining costly furnishings?

And did you ever notice how rain on a grade gullies out the side of the macadam, making it rough as the rocky road to Dublin, necessitating costly repairs?

By way of contrast, how would you like to live in a township *that bonds its macadam with Tarvia?*

The roads then are dustless, mudless, smooth—the air is pure and clean—the adjacent lawns green and fresh, and you can ride or walk in comfort.

What's the use of paying taxes to maintain roadways that not only create a nuisance but don't stand the stress of modern traffic?

If *your* town isn't a Tarvia town yet, why not get after the local road authorities till they make it one!

There's economy as well as civic beauty in tarviated roads.

Booklets regarding the Tarvia treatment free on request.

UNDERWOOD

"The Machine You Will Eventually Buy"

ductive of satisfactory results. The botanical side of the subject has been practically omitted, as have theoretical chemistry, the production of raw material, and mechanical tests of the finished product. In the special field which it covers, the work will furnish valuable aid to the chemist called upon to deal with India-rubber. Among significant chapters may be noted those on diluents, solid compounding materials, accessories, specific gravities, and analyses of manufactured rubber—both organic and inorganic. Several useful tables are appended.

FLYING. Some Practical Experiences. By Gustav Hamel and Charles C. Turner. New York: Longmans, Green & Co., 1914. Price, $3.50 net.

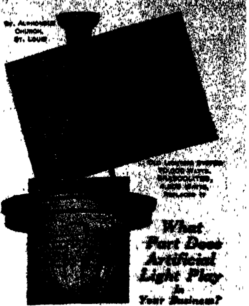
Mr. Hamel and Mr. Turner have written the kind of book which one has the right to expect from practical airmen. It gives us just that insight into the life of a pilot which most works on aeronautics have ignored. That flying is still more or less an acrobatic performance would seem to follow from Mr. Hamel's insistence upon good health and good physical condition. He is one of the few aviators that we know who frankly confess that exceptional steadiness of nerve and extraordinary coolness are indispensable elements in the personal equipment of every airman. It is a pleasure to see that the subject of accidents is not glossed over. Mr. Hamel unscathingly denounces pilots who leave everything to their mechanics and who take desperate chances. Particularly instructive is Mr. Hamel when he speaks of the vagaries of the air. "The air is so sensitive," we learn, "that it is affected even by the color of large patches of vegetation." Mr. Hamel has no illusions about the efficiency of the flying machine and particularly of the hydroaeroplane, as we now know it. "It is highly probable that all the sea-flyers tried in public hitherto are doomed to extinction," he tells us. "The efficient sea-plane is certain to be evolved. Meanwhile no nation possesses it." He bears out the views of the best designers when he says, "Beyond a general belief that all existing float contrivances are unsatisfactory and that a real airboat must be evolved, no one is able to foretell what will be done." While one may take issue with such rash statements as "there is not an aeroplane in the German military service that is not equipped with a bomb magazine and an instrument for sighting and timing," we must commend the book on the whole as a valuable addition to aeronautic literature.

PATENTS FOR DESIGN. By William L. Symons, LL.M., Member of the Bar of the District of Columbia, Lecturer on the Law of Trade-Marks and Patents for Designs, Washington College of Law. Washington, D. C.: John Byrne & Co., 1914. 184 pp. Price, $3 net.

The rapidly increasing importance of the subject of design patents requires that more attention and thought be directed to that branch of law and Patent Office practice confessedly not yet well settled and understood. The need for a treatise in which the provisions of the statutes, regulating the issuance of design patents and the subsequent enforcement of the rights acquired under them, are analyzed and considered in the light of Court and Patent Office decisions, has been supplied by the author. The text is arranged under six main headings, into which this subject can be logically divided for easy reference and study, as follows Design Patent Statutes, Subject Matter for Design Patents, Invention, Novelty and Infringement, Applications and Letters Patent, and Procedure in the Patent Office Under each of these headings, or main divisions, the author has carefully selected and grouped a large number of leading and decisive decisions rendered by the courts and the Patent Office, with a clear and full discussion and analysis of the most important of these. In grouping the decisions which are controlling on one or another feature of Design Patent Practice, the author was guided by the belief that the opinions expressed by the courts and writers on this subject, if held up and examined side by side and the exact points of existing differences noted, would lead to a clearer and better understanding of the particular questions involved. This book is but the third of its kind published in this country, the second appearing in 1889, of which Hector T Fenton, Esq , of the Philadelphia Bar, was the author The pioneer work was written and published in 1874 by William E. Simmonds, former Commissioner of Patents. There can be little doubt but that "Patents for Design" will meet with favor at once, and that it will be of inestimable value to all interested in its subject matter.

LA LUMIÈRE ELECTRIQUE ET SES DIFFERENTES APPLICATIONS AU THEATRE, installation et entretien. Par V. Trudelle, électricien. H. Dunod et E. Pinat, Editeurs, 47 et 49 Quai des Grands-Augustins, Paris, VI. In-8 de vi-295 pages, avec 80 fig. Broché, 10 francs; Cartonné, 11 fr. 50.

M. Trudelle has written a very practical book on electrical theater lighting for the architect or stage manager. There are only too few books upon a subject which is unfortunately still regarded as recondite The illuminating engineer has been so diligent in attacking the problem of house lighting that he has not as yet devoted much attention to stage illumination. Even if he were to do so, it is doubtful if he would succeed very brilliantly; for the illumination of the stage demands a technique of its own and a knowledge not only of electrical engineering, but also of theatrical effects. The author has had a very wide experience which is reflected in every chapter of his book. He discusses not only the effects to be sought, but also the machinery by which the effects are obtained.



What Part Does Artificial Light Play In Your Business?

You, your employees or your patrons depend upon perfection of illumination for working efficiency or stimulation of the buying impulse—install Brascolites. Cost of current is an overhead expense—economize on current and your gain is clear—install Brascolites. A large part of the demand for Brascolites is to *replace* either direct reflected, or indirect systems. Brascolite wiring installation *and* fixtures can be put in new buildings complete at a cost no greater than cost of wiring installation only of any other system.

BRASCOLITE

gives better light (more complete illumination) with a saving in current consumption and the *employment of fewer light units.* It is all in the fixture—so constructed that the bowl (see illustration) diffuses and the depolished plane above the bowl reflects—result, a shadowless, white, uniform, soft light over the widest area.

Note—the high efficiency "Nitrogen Lamps" can be used in all types of Brascolites.

Try A Brascolite For 60 Days

in your library, billiard room, hall, vestibule or private office—this intimate use will enable you to judge of its efficiency—convince you that it's needed in your business offices, store, etc. Your dealer will install the light—try it 60 days—if not satisfactory return it and get your money back. If satisfied and you order Brascolites for business equipment totaling $100 00 your dealer is authorized to refund to you the purchase price of your trial light.

Handsome Catalog Free

Illustrating and describing Brascolites of many designs—for all purposes of illumination. Send for it—state what your business is and for what purpose Brascolites interest you.

OFFICE SPECIALTIES

The "SANITARY" ERASER
Handy—Practical—Economical—Always Covered

THE SANITARY ERASER receives at its open end a strip of rubber ⅛ inch thick, of a width and length that of the holder. By slight pressure of the loop end, clean rubber is fed down until used; its narrow edge allows a letter or line to be erased without injuring another.

Two rubbers of best quality are made: one for typewriter and ink, one for pencil. *Handsomely Finished, Easy to Operate and "They Always Work."* EVERYBODY should have this NEW ERASER. Price 10c. Refills, Typewriter and Ink, or Pencil, 5c each. *Your Stationer.*

When ordering by mail, state whether Typewriter and Ink, or Pencil; enclose 2c extra for postage.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

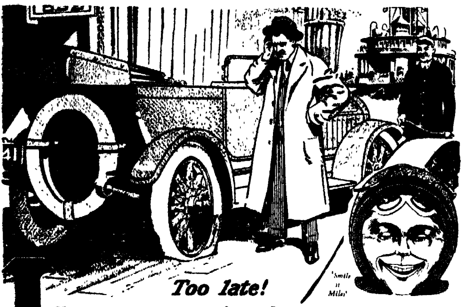
(12994) G. A. asks: As a reader, subscriber and admirer of your valuable paper, I now ask if there is any publication dealing with the contortion of vines. Surely enough they wind *from left to right in our hemisphere (going up)* Do their twists decrease nearing the equator, and then reverse from left to right to right to left? A. The twining of plants is treated in the botanies. It is usually the case that the same plant twines in the same direction at all times, but there are said to be plants which twine indifferently in either direction. All plants in our hemisphere do not twine with the sun, or from left to right. The morning glory twines in the opposite direction. It is said that plants in the torrid zone reverse their direction of turning quite frequently We have no information about this feature of plant life in the southern hemisphere. The phenomenon is called circumnutation

(12995) E. T. O'H. asks: If a person was at sea at 1,000 feet altitude, how far could he see? A. In the best table we have, the distance to which vision will extend from an altitude of 1,000 feet is given as 38.41 miles

(12996) S. R. asks: In the new edition of J Todhunter's "Algebra for the Use of Colleges and Schools," on page 438, is an enunciation of Fermat's Theorem which is as follows: If n be a prime number and N prime to n, then N^{n-1} is a multiple of n On page 439 of said book, paragraph 716, is a full and complete demonstration of said theorem. In query 12980 of April 18th, 1914, what is called Fermat's Theorem there only bears a small resemblance to the theorem as enunciated by Todhunter and assigned to Fermat, though on further investigation I may change my mind A. In reply to your letter we would say that Fermat had the habit of writing his observations upon the margins of the pages of the books he was reading, and in this way enunciated a large number of new statements upon many topics in mathematics The theorem which we quoted is known as Fermat's Greater Theorem, as we stated in our note, and to this and this alone the prize offered refers; it does not refer to any theorem which has already been solved You will note that the periodical from which we abstracted the conditions is the highest in authority in America, and doubtless the information given is reliable

(12997) W. R. L. says: I purposely asked that my question be submitted to your astronomer. I was under the impression that it was generally admitted that the earth being carried near hotter suns than ours, or, on the other side of it, being carried into regions remote from large and hot suns, was responsible for those great changes in the heat of the earth So I put it up to Mr Astronomer. I can't get away from the idea that some sudden change in temperature must be responsible for the imprisonment of the big animals in the ice in such perfect state of preservation as to have the food recently eaten still intact in the stomach A The writer of our reply to your former letter was our astronomer, not the one who prepares the monthly article, but the one who for many years has written all the replies to astronomical queries, so that his opinion is not that of a geologist, but of an astronomer. He would further say that no astronomer holds the view that the earth ever has been nearer to any other or hotter sun than the one around which it now revolves. Nor do astronomers believe that the earth could go near to such a sun and ever return to its orbit around our sun again. On the other hand, geologists have entirely abandoned the theory of sudden catastrophes, such as would catch and imprison a mammoth in the ice with the food in his stomach. He was caught in the ice, to be sure, but just as a climber to-day might be and lose his life with his undigested food in his stomach. Scott's "Geology," page 527, declares the doctrine of Catastrophism to be erroneous. Dana's "Manual of Geology," page 978, says that the elevation of the land in high altitudes is a sufficient cause for the glacial period. He does not even allude to the theory of catastrophes. No geologist or astronomer holds that sudden changes in the earth's climate have ever occurred.

(12998) I. C. McG. asks: Is there a school anywhere where children are taught the "sense of weight," so that they may know how much a pound or two pounds or five pounds are, just by the sense of weight, without having scales for proof? Why not have a grocer's clerk that can size up a package just as exactly as a bank cashier can size up a stranger? The child now is taught many more things than most of them can realize or profit by, but among them are many subjects no more important than the sense of weight. A. We quite agree with you that it is desirable to practice in the estimating of weights, but we do not think any such accuracy can be acquired as in the estimate of length by the eye. It does not seem possible that one can estimate a pound as accurately as a foot. Sensation in the eye is much more acute than the sense of pressure



You are a success, aren't you?
Your time is worth money, isn't it?

Can you afford to gamble with punctures—missing important engagements; losing by one such occurrence the cost of puncture-proof insurance for a year?

Play safe! Here is a tire that will protect you against punctures and lost time *against the high expense for inner tubes that punctures invariably cause.*

Lee PUNCTURE-PROOF OR MONEY BACK Pneumatic Tires

must prove absolutely puncture-proof—or you get back every cent you paid for puncture-proof insurance.

Back of that statement stands an absolute guarantee

Shall we send a copy of the Guarantee, and Pamphlet No. 6, with full details on construction and owners' reports of service?

Stop taking chances. Write today for this free booklet.

Lee Tire & Rubber Co.
Conshohocken, Pa.
Sold in all Leading Cities
Look up "Lee Tires" in your 'phone book

Note This Construction

Not a troublesome outside cover to kill resiliency —not an inner case to be attached

3200 steel discs imbedded *in* the tread

Each disc good for a smile —and far more than a mile

Every disc a guarantee against puncture

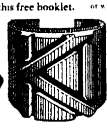
Discs overlap without touching Imbedded in rubber with fabric between layers—free from all danger of heating or tearing loose

Made like all other Lee tires, of the perfected

"Vanadium" Rubber

which so materially increases resiliency and mileage

Furnished either in regular tread or with the effective Lee



"ZIG-ZAG"
Non-Skid Tread
"Master of Slippery Situations"
Ask the dealer to show you this sturdier, more efficient non-skid (note cross-section).

Build the new way

Self-Sentering reduces cost—saves time

To all the advantages of concrete construction the important element of economy added by the use of Self-Sentering. It does away with expensive form work that was a necessity in the old method of concrete construction

For Self-Sentering is *both* reinforcement and form Every dollar spent on Self-Sentering construction is for *permanent* work.

With Self-Sentering, the highest type of roof—concrete—is an economic possibility

Two-inch concrete roofs, pitched, flat or curved are strong, rigid and fireproof Two-inch Self-Sentering partitions are rigid and great space savers Compared with the usual six-inch partition they add one square foot of floor space to every three lineal feet of partition

Figure the added total income from every floor thus made possible. Before you decide on plans discuss this modern construction with your architect or builder

upon a muscle, or the tension of a muscle. We should prefer the indication of the scales to the judgment of even an honest grocer's clerk in buying butter. There are schools in which weights are enclosed in boxes all of the same size and outward appearance, but the weights differ, and the student is to determine the weight. Such exercises are advantageous in developing the judgment of the student, and should be extended.

(12999) C. H. asks: I wish to ask if you can give me answers to the questions below or tell me in what book I can find them 1 How can the force against an object exerted by the impingement of a ray of light be calculated, and how measured? A. You will find an abstract of a lecture by Prof Nichols, who succeeded in measuring the pressure of radiation, in our SUPPLEMENT No. 1539, and other valuable articles upon the same subject in SUPPLEMENT Nos. 1525, 1814 and 1958, which we will send for ten cents each, mailed 2 Where can I get a radiometer (one of those glass affairs containing a vane-wheel which spins when exposed to light) and what is the cost of one? A. You can buy a radiometer from any dealer in physical apparatus. 3 What books or papers have you for sale on selenium cells and transmission of light? A We can furnish you with many papers on selenium We name SUPPLEMENT Nos. 1430, 1719, 1912, 1881, 1882, 1883, 1897, 1914, and the SCIENTIFIC AMERICAN, Vol 102, No. 8, and Vol. 107, No. 21; price, 10 cents each, mailed.

(13000) F. M. H. asks: Desiring to gain the date of a few modern inventions, I have been recommended to you Can you give me the date and name of the inventors of the following Steam power, electricity as a power, telegraphy, the first steam vessel? I would like the date of the first alphabet. A As a rule, the dates of the "first use" of most things are involved in much obscurity, since no note is taken of such matters at the time Their importance is not realized by the persons engaged in the events The history of the steam engine is given in the "Encyclopædia Britannica," vol 25, page 818, which you may find in your public library The earliest use of steam for power is described by Hero of Alexandria, about 130 B. C The first useful steam engine is usually ascribed to Edward Somerset, at least its description, though perhaps not its construction, in 1663. The first commercially successful engine was that of Thomas Savery, patented in 1698, in England Newcommen followed in 1705, and in 1763 Watt so improved Newcommen's engine as to make it really a different machine, and from Watt the modern steam engine is usually dated But it was not till 1829 that the locomotive was successfully brought out by George Stephenson, though many competitors were in the field The early inventors of steam propulsion on the water are given in SCIENTIFIC AMERICAN, vol. 101, No 13, price ten cents You will find in that paper cuts and descriptions of the performance of Johnathan Hull's steamboat, 1737. A letter of a correspondent regarding this boat in the SCIENTIFIC AMERICAN, vol. 101, No 18, which goes to prove that this boat was built and performed real work, should be read. This seems to have been the first steamboat Between 1780 and 1807, the date of Fulton's "Clermont," there were other steamboats built, in America and Europe, which are pictured in the paper referred to above. You will find these fully described in Thurston's "Growth of the Steam Engine," which we send for $2 50 postpaid The first practical recording telegraph instrument was that of Morse, in 1835, to whom we also owe the dot and dash alphabet. The first use of electricity for power was when an electromagnet was used to lift a weight, the date of which is not known It might be claimed that the first time rubbed amber lifted a piece of thin paper, about 600 B C, should be taken as the proper date for this The first motors were run by batteries and antedate the invention of the dynamo. Possibly the first electric motor was that of the Abbe Salvatore del Negro in Italy in 1830. Thomas Davenport, a blacksmith of Brandon, Vermont, in 1835 constructed a car which was run by a motor operated by a battery, which was carried on the car The early efforts in the line of electric railways are given in the "Encyclopædia Britannica," vol 27, under the caption Traction. Our alphabet is derived from the Greeks, and they are believed to have obtained their letters from the Phœnicians The date of this is not known.

(13001) L. B asks: On the night of April 13th, on a farm about ten miles outside Johannesburg, I witnessed a perfect lunar rainbow It was a dull white in color, and near the original there appeared the lower part of a second bow As a reader of your paper, I should be glad to know if this phenomenon would appear under similar conditions, i e, a rain squall beating up from the west and the moon rising in a clear sky in the east, in any part of the world, or whether it was due to the nature of the atmosphere here, as Johannesburg is situated 6,000 feet above sea level A Lunar rainbows are not common, nor can they be called very rare. The writer has seen several. They are as you describe, not bright enough to show the colors of the solar rainbow, unless a faint red and yellow They are sometimes seen at sea, and the altitude of the place would have no influence in their formation

(13002) H. K. asks: Some years ago, I recall reading an article in the SCIENTIFIC AMERICAN on the processes of metalizing flowers and insects. I am anxious to know the process, and would like to know if you can furnish the formulas and working knowledge, or advise me where I can get it? A. You will find instructions for electroplating flowers and other soft objects in the SCIENTIFIC AMERICAN, vol 99 No 22, and in SUPPLEMENT, Nos. 1716 and 1749, price ten cents each, mailed. Fuller instructions are given in Watt's "Electro-Plating," Chapter VI, which we send for [illegible] postpaid.

(13003) R. E. W. asks: Does the moon have any effect on the growth of vegetables? Does it make any difference when potatoes are planted in reference to the moon? I have been told by several successful farmers that the time to plant potatoes was in the dark of the moon. If planted in the light of the moon, they would all grow to tops. Does the moon have any effect on the killing of pigs for pork? Some claim that if killed during a certain time of the moon the meat will all curl up when fried, other times it will not. Does the moon have any effect on the weaning of children or stock? This all sounds very foolish to me, as I can see no connection between the moon and garden stuffs or pigs and children The moon is there all the time, but the people I talked with were very indignant when I doubted them. A. There is not a shadow of evidence of a scientific nature to show that the moon has the slightest influence on the weather, or the growth of potatoes, or the cooking of pork, or the weaning of stock. When you think of it that thousands of hogs are killed every day in the year, moon or no moon, in the large slaughter houses of the West, it is evident that the packers have no respect for the moon in selecting a day for the killing of hogs. In the other matters of your inquiry, the same is true. Men do not generally look to the moon for portents for planting They plant when the ground is in the proper condition

(13004) A. J. deF. asks: In your issue of May 2nd, 1914, page 368, Mr. Henry Norris Russell says, "at a distance of 1,255 astronomical units, or 117 million miles." J. H Poynting in "The Earth," page 36, says, "Astronomers use as the unit the distance which light travels in one year at the rate of 186,000 miles per second, or 5.8 million million miles" Please set me clear about this. A. Your difficulty as to units in astronomy is easily adjusted. Both Prof. Russell and Prof. Poynting are correct, since they are referring to different units. The "Astronomical Unit" is the mean distance of the earth from the sun, and this is used in expressing distances in the solar system. Its latest determination is 92,877,000 miles. Prof. Young in his "Manual of Astronomy," page 497, says, "The distances of the stars are so enormous that the radius of the earth's orbit, the astronomical unit hitherto employed (meaning by hitherto, in his book thus far) is too small for a convenient measure. It is better, and now usual, to take as the unit of stellar distances the so-called 'light year,' i e., the distance which light travels in a year." Now referring to Prof Poynting's book, page 36, it is evident that he is referring only to the unit of the stellar distances, and not to distances within the solar system, with which Prof Russell was dealing in the article referred to above We trust this makes the matter clear. We express short distances in feet, longer ones in miles. In just the same way the Astronomical Unit is used for the relatively short distances in the solar system, and the Light Year for the spaces between us and the stars.

(13005) J. M. asks: I wish to know how to keep flowers that are cut from withering so fast. Is there anything that can be put in the water, or some special treatment? A It has been said that flowers will keep much longer without fading, if a little ammonium chloride is put into the water in which they are placed The cut ends should be fresh when the flowers are put into the water. An end of a stem which has been seared and dried cannot absorb water, and the flower must fade. It is best to cut the stems off under water and not allow the air to strike them at all The protoplasm of the plant is very sensitive, and it is upon its power to imbibe water that the life of a plant depends.

(13006) R. W. N. asks: Please let me know what you know about cleaning silver and gold by the use of a small zinc plate to which a strip of tin is attached I have used this successfully in cleaning silver in a granite pan, but to-day a man informed me that if a person used a pan made of any other metal than zinc, the silver on the ware placed in the vessel to be cleaned, would be removed and deposited on any part in the pan in which the base metal was exposed. For instance, if the enamel happened to be off in some spot, and the iron exposed, it would plate the iron over with silver removed from the silverware; and if a tin vessel was used, if there was a spot where the iron happened to be exposed, the silver would be plated over it and would continue to plate and replate over the silver already deposited thereon, thus removing silver from all silverware placed in such a pan with the zinc plates for cleaning. A. In the use of the silver and gold cleansing process, it is necessary to have a metal dish, or better a metal plate in an earthen dish, which is electro-positive to silver. It is not difficult to find such metals, since silver and gold are negative to most of the metals. Presumably, most of the solutions employed contain nitrate of silver, which is deposited on the silver article by electrolysis, a feeble current being set up in the liquid Thus a plating action is produced. The list of metals given in the "Standard Electrical Engineers' Handbook," price $4, is as follows: Aluminium, zinc, tin, lead, iron, copper, silver, gold. Any metal which precedes silver may be used, but the farther away from silver the metal is in the list, the stronger the action will be. From this it is seen that aluminium is the best metal to be had for the plate, and zinc is the next in value. It is also to be seen that the plating action would not be reversed by the use of iron or steel in the dish in which the plating is carried on. It is more common to use an earthen dish and to place in it a sheet of aluminium, with which the silver articles are brought into contact.

The Most Powerful Locomotive

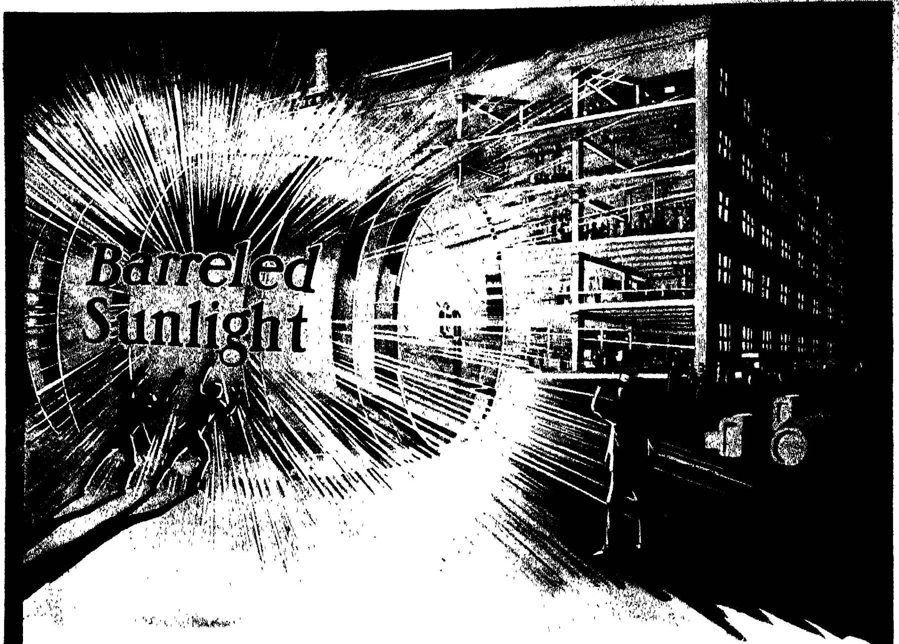
Successful Test of Langleys' Flying Machine

New York's Polluted Waters

Vol. CX. No. 24
June 13, 1914

Munn & Co., Inc., Publishers
New York, N. Y.

Price 10 Cents
$3.00 A Year



Buy your sunshine by the barrel

Fill your factory with it. If your ceilings and walls *absorb* instead of *reflect* light you are getting only a fraction of the light you ought to have. "Barreled Sunlight" will give you ALL of it, lengthen your daylight day and cut down your lighting bills. It will increase your present lighting 19 to 36 per cent. Paint your ceilings and walls with

RICE'S MILL WHITE

The only oil paint (without varnish) giving a glossy, tile-like finish

It will fill your factory with sunshine. It will reflect every ray of your natural or artificial light down on to your machinery and into the dark corners of your plant. Its glossy surface will not absorb light or collect dust, dirt, germs and odors like a flat paint. It can be washed like tile.

Rice's Mill White will not scale and require frequent renewals like a cold-water paint. It will not "alligator" and crack under the jar of machinery like a varnish paint. It flows easily under a 4" brush; two coats equal three of lead and oil. *It stays white longer than any other gloss paint.*

The Original Mill White

Rice's Mill White made a trade name of the words, "Mill White." *There is no substitute for it.* None of its imitations has its elastic, permanent qualities No other paint manufacturer can use the Rice process Rice's Mill White for ten years has proved itself unequalled for illuminating power, sanitary qualities and low ultimate cost

Rice's Mill White is sold direct from our factory, in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover,

The Erie "pusher," largest locomotive in world. Weight, 853,000 pounds; tractive effort, 160,000 pounds.

The World's Largest Locomotive

THE engineers and naval architects are doing some big things in the way of construction just now, as the recent arrival of the "Vaterland" and the "Aquitania" at this port has shown; and the illustrations which we present of the great Erie freight locomotive give evidence that in that other great field of transportation, the railway, the engineer is also building in ever-increasing sizes and weights. This most interesting locomotive has recently been completed for the Erie Railroad from designs by G. R. Henderson, consulting engineer of the Baldwin Locomotive Works. It is the heaviest and most powerful locomotive ever constructed, its total weight being 853,050 pounds. The greatest advance of this over existing freight locomotives has been in the matter of tractive effort. Hitherto the most powerful freight locomotive was what is known as the Virginian Mallet, which, when working compound, has a tractive effort of 115,000 pounds. The tractive effort of the new Erie locomotive is 160,000 pounds, or a direct pull on the drawbar of eighty American tons. The locomotive has been built for the pusher service on an 8-mile stretch of grade east of Susquehanna, Pa., which has an average rise of 56 feet to the mile. The new locomotive, which is known as the Triplex Compound, will take the place on full tonnage trains of three separate pushers, as now used.

It will be seen at a glance that the novelty in this locomotive consists in the fact that, in addition to the two separate engines placed under the locomotive proper, which are the characteristic feature of the Mallet type, a third engine has been placed under the tender, whose weight is thus brought into service for tractive effort. An interesting feature is the fact that the three locomotives with their sets of coupled drivers are identical in dimensions, all cylinders being 36 inches in diameter by 32 inches in stroke, and all having 16-inch piston valves and the Baker valve gear. Steam at a pressure of 210 pounds to the inch is led to the central pair of cylinders. The exhaust steam from the cylinder on one side is led to the forward low-pressure pair of cylinders, and that from the cylinder on the opposite side is led to the after pair of low-pressure cylinders. The ratio of expansion is therefore 1 to 2.

The boiler is of enormous proportions. At the front end it is 94 inches in diameter and at the dome ring 108¼ inches in diameter. The firebox, of the radial stay type, is 162 inches long and 108 inches wide at the mud ring. The locomotive is fired by a mechanical stoker. Superheated steam is used, of course, and the Schmidt superheater, the largest ever applied to a locomo-

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The One Great Lesson of the St. Lawrence Disaster

IN the case of great calamities, such as the sinking of the "Empress of Ireland" with a loss of over 1,000 souls, there is a danger that the one great lesson of the disaster may be lost sight of in the consideration of questions of relatively minor importance. The alarming fact in this case is that this comparatively new and very fine ship went to the bottom in *fourteen minutes after the collision.*

The large modern passenger steamer carries a small townful of people. In the designing of such a ship there are many requirements to be met, but there is one requirement which in importance transcends all the others, and this is that, if from two to five thousand people are to be committed to her keeping, and she is to be sent across many thousand miles of ocean water, she should be so built that she is practically unsinkable.

Let us suppose that no such vessel had ever been constructed, and that, *to-day*, for the first time, the problem was put up to the naval architect and the engineer to provide a 20-knot ship capable of carrying several thousand people across the Atlantic. It is perfectly certain that, if no restrictions of a commercial kind were imposed upon him, the designer, realizing the priceless value of the human freight that was to be committed to her care, would see to it that her construction was such as to render her practically unsinkable by any of the accidents of ocean travel. Having built her so, he would then proceed to provide the necessary accommodations for boilers and engines, and for the housing and comfort of her passengers and crew. As a matter of fact, when the first of the great ocean liners, the "Great Eastern," was under consideration, her designers, Brunel, the engineer, and Scott Russell, the naval architect, did make this the first consideration. They built the ship with a double hull, one within the other, with a suitable space between them, said space being divided and subdivided into a multitude of watertight compartments. This double hull extended from stem to stern, and it was carried some ten to twelve feet above the water-line, at which point it was covered in by an iron, watertight deck. The double hull as thus provided was subdivided by a large number of stout watertight bulkheads extending transversely across the ship. Also there were run longitudinally through the ship, two bulkheads which served still further to subdivide the transverse compartments.

Unfortunately, this great ship was ahead of passenger and freight traffic requirements of her day; she could not get a sufficiently large passenger list nor sufficient freight to make her a paying proposition. There was a return to smaller ships, but most unfortunately for the safety of ocean travel, the ocean liners, built from her day on, were constructed without that proper and very solicitous care which Brunel exercised in the endeavor to make this ship safe and practically unsinkable. That Brunel was satisfied that he had succeeded in building a safe ship is shown by his "notes on the strength and safety of the 'Great Eastern,'" which he prepared for the stockholders and directors just before her launching, in which he said, "No combination of circumstances, within the ordinary range of probability, can cause such damage as to sink her."

In the forty years of shipbuilding succeeding the day of the "Great Eastern," the shipbuilder eliminated many of the structural elements which made that fine ship so safe. The double hull was confined to the bottom of the ship, the sides, from the turn of the bilge up, consisting merely of a single thickness of plating. The longitudinal bulkheads were omitted, as were also the watertight decks.

Now, so far as the saving of the lives of the passengers is concerned, the double bottom is not so important as the double sides. As a rule, in case of puncture of the outer shell through running upon rocks, the ship remains afloat and the passengers can be saved; but in the event of a rupture, as in the case of the "Titanic," of the single shell plating at the sides of the ship, experience shows that if the damage be extensive, the ship is doomed.

As matters stand to-day, only a few of the large ocean liners engaged in the Atlantic trade embody the principles of safety which Brunel put into the "Great Eastern." The "Kaiser Wilhelm der Grosse" and the "Cecilie," of the North German Lloyd, are so built, as are also the "Imperator" and the "Vaterland" of the Hamburg-American Line. The "Olympic," after the disaster to the "Titanic," was rebuilt at a cost of a million dollars, and she now carries an inner skin, lofty bulkheads, and watertight flats below the water-line. She is now a safe ship. The "Mauretania," "Lusitania," and the new "Aquitania" of the Cunard Line are safe; for they too have been provided with an inner skin in the shape of the inner walls of the coal bunkers, which extend throughout the greater portion of the length of the ship. The new "Britannic," due here in the Autumn, will carry an inner skin. Outside of these ships and perhaps a few others, practically the whole of the fast and large passenger-carrying ships on the Atlantic and Pacific Oceans are without an inner skin, and in case of serious collision, are liable to suffer the same fate as the "Empress of Ireland."

In our last issue we drew attention to the very serious fact that, although the recent London International Conference on Safety at Sea advocated higher transverse bulkheads terminating in a watertight deck, it did not, as it should have done, specifically call for the provision of some form of inner skin. We consider that it is a great misfortune that this distinguished board was not composed more fully of purely technical men—naval architects and engineers—who would have considered the question of making ships absolutely safe upon its technical merits and without a too tender regard for the first cost of construction. It is not too late to make the necessary change before the Convention is ratified. The cost of inner-skin construction is not prohibitive by any means, and if it will prevent, as it certainly will, such sudden and wholesale snuffing out of the lives of passengers as occurred in the "Empress of Ireland," considerations of humanity demand that inner-skin construction, in some form or other, should be made absolutely obligatory in the case of ships that carry large passenger lists.

Where the lives of a whole townful of people are concerned, the ships that carry them should be made fool-proof. This can be done; for it is a mere matter of mechanics and construction. Certain it is that the human element and all the risks which come with it can never be eliminated. When two ships, such as the "Empress of Ireland" and the "Storstad," which sight each other some two miles apart, and are in constant conversation during a passing fog-cloud, through well understood signals, nevertheless blunder into an inexcusable collision, surely it is time for the public to demand that the ships in which they trust their lives shall be made fool-proof. Throughout the whole of the official investigations which will be made of this terrible calamity, for Heaven's sake, let everybody, from Lord Mersey down, bear in mind the fact that the great lesson of the calamity is that we must safeguard against the frailty of the human element by making such horrors as this *mechanically* impossible.

Lightning Protection for Dwellings

EVER since Benjamin Franklin invented the lightning-rod our ideas as to what constitutes effective protection for buildings have undergone constant revision. The cheap and improperly installed lightning-rods sold to farmers by enterprising agents were soon found to be worse than useless, and, in the reaction that set in against them, the modern dwelling house has usually been left without any protection. This has developed a situation that is both critical and serious, because we are now building our houses in such a way as greatly to increase the hazard that existed heretofore.

The modern skyscraper seems to have worked out its own salvation, because it is constructed on correct principles. *Its massive steel frame, its metallic roof, and its grounded conductors form a lightning protection that is as perfect as could be desired.*

In the modern suburban house, on the other hand, we are persistently violating the principles that have made *the skyscraper so safe, and the increased damage that* has resulted abundantly testifies that we are paying the penalty for such infraction of Nature's laws. Houses of the class mentioned are seldom provided with metallic roofs. Shingles, slates, and asbestos shingles are the predominating materials, and the leader pipes frequently terminate several inches above the ground. These things in themselves, however, do not constitute the increased hazard to which reference has been made. This comes from the steam or hot-water heating system, where we construct within the shell of the building a system of massive conductors running from cellar to attic. These pipes are, for the most part, very straight, *forming paths of low impedance* to the passage of high-frequency discharges, and they are also directly connected to the underground piping of the water-works system, which forms a most effective "capacity ground." A more attractive path for a lightning discharge it would be difficult to imagine, and yet how can the lightning take advantage of it? *Only by puncturing the roof or side-walls of the building and probably setting them on fire!*

The writer has seen so many buildings damaged in just this way that he is moved to point out the danger, and to suggest as a remedy that such a heating system should be provided with at least one or, preferably, several pieces of pipe extending from the top-floor radiators straight up through the roof and terminating with capped ends. It would seem, from careful consideration of the various factors involved, that the danger will, by this expedient, be greatly lessened.

Climatic Fluctuations

THE study of real or supposed changes and oscillations in climate possesses a peculiar fascination for many minds, if one may judge by the flood of literature that has appeared on this subject. The idea that the climate of any region has definitely and permanently changed within a generation or so, although firmly fixed in the mind of the average layman, is not held in honor in scientific circles. On the other hand, few meteorologists have been able to resist the temptation to hunt for periodicities, correlations, and the like, in the ups and downs of climatic curves from year to year, and to seek the clue to these fluctuations in such far-reaching agencies as variations in solar radiation, volcanic eruptions, or what not. Such investigations, however, are often vitiated by hasty assumptions from the records of a limited number of stations as to what has occurred in the world as a whole. In order to know, for example, whether world-temperatures fluctuate in the same way as the sunspot period, we must have before us some accurate delineation of these temperatures which will not obscure the fact that a warm year in Europe may coincide with a cold year in South America, and so forth. It probably never happens that the temperature of the whole world is above normal at the same time; what we have to deal with, in investigating world-temperatures, is variations in the size and intensity of the regions in which excessive temperatures *do* occur. These are what Mr. Henryk Arctowski has called "pleions," and his method of charting the pleions of temperature and other elements from year to year is one of the most fruitful devices known to meteorology. First set forth in his "Enchainement des variations climatiques" (Brussels, 1909), it has been utilized in this author's numerous contributions to the *Bulletin of the American Geographical Society* and other journals. His latest study of "pleionian" variations appears in the *American Journal of Science* for April, 1914.

Temperatures of the Stars

DURING two years, Rosenberg has studied photographically the spectra of the seventy most brilliant stars in the northern hemisphere, from the first to the third order of magnitude. By a comparison of their spectra it is possible to deduce their temperatures. The results obtained agree well with those of Wilsing and Scheiner; stars of the helium type are the hottest, and the red stars are the coolest. As a specimen, the following temperatures are quoted: Sirius, 27,000 degrees; Vega, 22,000 degrees; Algol, 12,000 degrees; Arcturus, 3,000 degrees; Aldebaran, 2,000 degrees.

From the aspect and relative displacement of the spectral lines an idea may be formed of the pressure conditions in the atmospheres of the stars studied. Thus Adams has found that in the light-emitting atmosphere of Sirius the pressure is twelve times that existing in the solar photosphere, which confirms the hypothesis that Sirius is a simple mass of gas, without a defined surface of condensation.

William A. Carroll

IT is with much regret that we announce the death of Mr. W. A. Carroll, who, for many years, was connected with the advertising department of the SCIENTIFIC AMERICAN as its Western representative, which field he covered in a most satisfactory manner, making for himself a high record of efficiency in this work. His close attention to business, genial manners, and good-fellowship gained for him a host of friends in the West, who will, we are sure, regret with us his untimely demise.

Engineering

Proposed Inter-terminal Line at St. Petersburg.—According to the Engineer, it is proposed to construct a belt line of railway connecting up the various lines entering the city of St. Petersburg. The line will serve for the transfer of merchandise and passengers from one railroad system to another, and the total length will be about 53 miles.

High Speed on a Maiden Trip.—During her maiden trip to this port last week, the new Cunard steamship "Aquitania" steamed during a single day 602 miles, an average of 24.24 knots. On her trial trip she averaged for a few miles slightly over 25 knots. The fastest average for the whole Atlantic trip of 26.06 knots was made a few years ago by the "Mauretania."

President Wilson on the Merchant Marine.—After a call of the National Foreign Trade Convention at the White House the President was quoted as saying: "I am sure that I speak the conviction of all of you when I say that one of our chief needs is to have a merchant marine. Because we have to deliver our goods in other peoples' delivery wagons their goods are delivered first and our goods are delivered incidentally on their route."

Railway Accident Statistics for Three Months.—During the three months ending September 30th, the Interstate Commerce Commission states that 211 passengers were killed and 4,011 injured in train accidents in the United States. At this rate the total for the year would be 844 killed and over 16,000 injured. The accident *Bulletin* says that 67.6 per cent of the derailments were due to defective equipment and defective roadbed.

The Spaciousness of Modern Liners.—As showing the spaciousness of the largest of the modern ocean liners, attention is drawn to the ballroom on the "Vaterland," which is 80 feet in length, 58 feet in width and 21½ feet in clear height. In spite of its great span, this room has no supporting columns whatsoever, the roof being carried by overhead girders, extending from side wall to side wall. The dining-room is 135 feet long, upward of 100 feet in width, and it has a maximum height of 30 feet.

Cost of Panama Canal in Lives.—In a letter to Hon. George M. Young, Representative in Congress, Col. Goethals states that from May, 1904, to March, 1914, 1,219 lives were lost on the Panama Canal through accidents. This total covers only those deaths which resulted from accidents happening on the work, except that it includes 167 deaths from accidental drowning, all of which did not occur on the work. From August, 1908, to March, 1914, the accidents resulting in injuries reached a total of 25,101. Mr. Young called the attention of Congress to the fact that the loss of life through accidents, as here recorded, was greater than that during the war of 1812, or during the Mexican war.

A Difficult Engineering Feat.—What is considered one of the most difficult bridge engineering feats yet attempted was the removal from the Williamsburg Bridge trusses of the existing end pins and the substitution of larger pins, without seriously interfering with the traffic. For some time reconstruction of the floor system of the bridge has been under way, in preparation for the heavy subway trains of the Dual Subway System. As part of this work it was necessary to remove the existing 10-inch pins from the trusses at the towers and substitute 13-inch pins of nickel steel. These pins are 40 inches in length and weigh 1,500 pounds. It was necessary to drill out the ends of the steel girders to the enlarged dimensions before inserting the pins.

The Hydro-Aeroplane at Vera Cruz.—Capt. Washington I. Chambers, U. S. N., in a lecture to the members of the University Club of Washington, stated that the hydro-aeroplanes had proved their usefulness in military operations around Vera Cruz and elsewhere. Particularly had they shown their value in ascertaining whether or not harbors were mined. The captain stated that not only is it possible to see mines plainly, but they can be easily photographed from the aeroplane. Recently, mines were planted on the Pacific Coast and the commander of the Pacific fleet was notified to that effect. The aeroplanes were sent out to search for them, the aeronauts having no information as to the vicinity in which they could be found. Nevertheless, they had no difficulty in locating the mines.

A Suggestion in Economy.—According to the *Railway Gazette*, an American railroad recently sent a train over its system to collect scrap material and odds and ends of every kind, the train carrying a divisional superintendent and his staff. Scrap and obsolete material was collected to the amount of 147 car loads, valued at $42,000, and after deducting the cost of labor, train expenses, etc., there was a net gain of $39,000. As showing the conditions, twelve bottles of ink were found at a small station where one bottle would suffice for a year, and at another point fifty non-insulated bridle rods were found at a station on territory which was track-circuited throughout. Useless at such points, these materials were serviceable elsewhere.

Science

Dr. Richard Assmann, the dean of German aerologists, has retired from the directorship of the aeronautical observatory at Lindenberg, where he is succeeded by Prof. Hergesell, late of Strassburg.

The Edward Longstreth Medal of the Franklin Institute has been awarded to Prof. William J. Humphreys of the United States Weather Bureau, for his paper on "Volcanic Dust and Other Factors in the Production of Climatic Changes and Their Possible Relation to Ice Ages."

Coins for a Leper Colony.—The Philippine government has minted a special coinage for use in the Culion leper colony. The coins are of aluminium, and include pieces of one peso, and twenty, ten, five, one and one half centavos. They are accepted at face value for all business carried on within the colony, but are of no value elsewhere.

An Encyclopædia of the German Colonies is in course of preparation under the general editorship of Dr. H. Schnee, governor of German East Africa, and is to be published in Leipzig. About seventy specialists will contribute articles on colonial politics, geography, ethnology, geology, mineralogy, zoology, mining, agriculture, communications, missions and all other topics connected with Germany's great colonial empire.

Agricultural Meteorology in France.—The project of establishing an office under the French government devoted to the study of agricultural meteorology (distinct from the Bureau Central Météorologique) has been under discussion for several years. A technical commission on this subject has at last been established by a ministerial decree of January 6, 1914, as a branch of the Direction Générale des Eaux et Forêts, under the Ministry of Agriculture. It consists of thirty members, who are nominated for three years.

A Daily Wireless Weather Bulletin for the Great Lakes was inaugurated by the United States Weather Bureau on June 1st. It is distributed broadcast by the naval radio station at Radio, Va., a few minutes after 10 P. M., immediately after the bulletin for the North Atlantic and Gulf of Mexico, which has now been sent out daily for some months. The new bulletin, which is for the benefit of mariners on the lakes, gives the weather conditions prevailing at 8 P. M. of the current day at Duluth, Marquette, Sault Ste. Marie, Green Bay, Chicago, Alpena, Detroit, Cleveland and Buffalo, and a forecast of wind and weather conditions for the upper and lower lake regions for the following 24 hours.

An International Hydrographic Campaign in the North Atlantic Ocean is planned in connection with the formal opening of the Panama Canal. At the suggestion of Prof. Schott of the Deutsche Seewarte, all European countries that are to send men-of-war to Panama for the opening ceremonies have been asked to make a complete hydrographic cross-section of the ocean along their routes. According to this programme, three professional oceanographers would be carried on each of the ships, and the ordinary time of crossing would be increased by about a week to enable the work to be thoroughly carried out. The Prince of Monaco has been asked to take part in the campaign.

The Effects of Smoke on Cattle were the subject of an inquiry addressed to farmers in the vicinity of Leeds, in connection with the investigations being carried out at Leeds University concerning the effects of atmospheric pollution on vegetation. It was learned that the effects of a smoky atmosphere on both cattle and horses are marked: young stock do not thrive, while older animals require more food and greater care than those living in a less contaminated atmosphere. The effects are partly due to the respiration of the smoke-laden air, and partly to the inferior quality of the grass growing under such conditions. The raising of sheep is even more difficult, because of the depreciation in value of the wool due to the smoke, and is rarely attempted near Leeds.

Freezing a Patient to Cure Him of Consumption.—Freezing of living persons is the somewhat heroic remedy proposed by the Russian scientist Bachmetieff, for the Koch bacillus is killed at 6 deg. Cent. below freezing point, it being the cause of tuberculosis, so that by congealing the person affected with the disease the microbes are all killed. Then he brings back the subject to life by a very gradual re-heating. He has already succeeded in applying his method to various animals such as the rat and others by producing artificial respiration in them at the same time that the freezing process is going on, and he thus produces suspension of life by cold which is of great interest to science and may also prove of much utility. Freezing of cattle in Winter would thus preserve them without food, and they could also be transported over great distances when in this state. Many other applications of the idea can be imagined. Of course, the method has not as yet been applied to the larger animals nor to living persons, but in principle this does not appear to be impossible, and it now remains to be proved whether a human being can be actually frozen and then brought back to life.

Aeronautics

The Trial of the Langley Aerodrome.—Our correspondent at *Hammondsport informs* us that the flights of the old Langley machine have thus far been brief hardly less than ten seconds. Hence they are not conclusive. Mr. Glenn H. Curtiss has about decided to substitute a more powerful engine—probably his eight-cylinder—and a single-tractor screw, since the present plant has not quite thrust enough for forty per cent extra weight due to floats and the trussing between them and the steel frame. The present arrangement has about twice the resistance of the original machine.

Pending Legislation for Army Aviation.—The passage by the House of Representatives of the Hay Bill looking to the establishment of a division relating to flying in the office of the Signal Corps encourages army officers because of what might be termed the official status thus given to aviation in the military establishment, especially as there is much hope for favorable action by the Senate on the bill.

American Hydro-Aeroplanes Abroad.—Philip Hoffman, the Secretary of Embassy at Constantinople, reports that the Ottoman Ministry of Marine has recently had under consideration the desirability of purchasing one or more hydro-aeroplanes or flying boats, one of which, under American auspices, has lately made several private trial flights near Constantinople with success, and it is reported that successful trials have also taken place in Russia.

Aeroplane Racing.—According to the ideas of Mr Paris Singer, one of the prominent Englishmen living in the Riviera, the time-honored horse race will be supplanted by the aeroplane race. Each proprietor will own a number of aeroplanes and have one or more pilots in his employ, and racing events will be held under the same conditions as for horse races, and no doubt with more excitement. To start the movement, which would be more of a success in the Riviera than elsewhere, owing to the favorable climate, he has now engaged the crack pilot, Maicon, and will purchase several fliers. Maicon will act as chief and will train other pilots if need be. Should others take up this idea, each proprietor will have his fleet, and there would be organized suitable racing events between them, or, on the other hand, the fliers will be sent to take part in various official contests. He expects to use watercraft largely for sailing upon the Mediterranean.

Germany's Air Strength.—It appears that Germany now has 14 large airships, including 7 Zeppelin destroyers. Their size is on the average 600,000 cubic feet, and they carry 600 to 800 horse-power motors. A crew of 15 to 20 men is carried, also 8 tons net load, comprising 1.5 tons of projectiles. As regards secondary questions, these are now very well organized. Between Berlin and the frontier are thirty balloon sheds and grounds with sheds of 600 feet length in many cases, pivoting upon large platforms so as to face the wind and allow the airships to enter safely. Balloon supplies are well looked after, and special railroad cars are fitted out with sets of steel hydrogen bottles mounted upon a common discharge pipe. Such cars are kept stationed in works which furnish hydrogen as a by-product, and are ready to be sent out upon the railroad wherever they are needed. The German army counts considerably upon night trips with the airship or aeroplane fleet, and all the needed measures have been taken to allow of doing this in good condition, the landing grounds being lighted at night and a system of colored electric flashes, as in lighthouses, shows special signals for each of the grounds. A powerful electric searchlight on board the airship also lights up the ground when landing.

The Third Russian Aeronautic Congress.—An interesting event was the third Russian Aeronautic Congress held at St. Petersburg. Numerous papers were read. In the military section we note the communications made by Lieut. Iatsouk upon rational training of army and navy pilots, and a paper by Gen. Kaulbars upon the necessity of different types of aeroplane. Col. Gatovsky presented a memoir on organization of the aerial fleet. The technical section had papers on the state of aviation at the present time, aerial propellers and the work of the Technological Institute aero-dynamic laboratory. Prof. Remne treated of wind pressures on various surfaces, and Prof. Sarkovsky of aero-dynamic comparisons among aeroplanes. In the section which concerns general and sporting questions, M. Chetamine read a paper on the situation of the aeronautic industry in Russia and other countries, and upon organizing of aerial militia. This last topic was taken up and completed by the Aero Club Secretary Weigueline in his paper on private aeroplanes in connection with military use. A leading paper of the congress was the report made by Engineer Berk upon use of railroads for organizing observations on the passage of aeroplanes and installing of landing places. It is thought that the present congress will be the starting point of a considerable development of aviation in Russia, especially as concerns military questions.

The Launch of "Shamrock IV"

A Yacht Designed on Strictly Utilitarian Lines

OF great interest to American readers will be the photographic views which we publish of "Shamrock IV." The first impression one gains from the pictures is that designer Nicholson, realizing how closely contested are the present-day races for the "America's" Cup, determined to design his yacht along lines of the strictest utility. During the process of planning a purely racing yacht, such as "Shamrock IV," in which the question of ultimate speed is dependent upon the best possible combination of form, lightness, and strength, occasions will arise when beauty must be sacrificed to utility, or, to put it in another way, when the artist in the naval architect will demand one thing and the engineer in him will demand another. Evidently designer Nicholson decided that the only possible chance to win the 'America's' Cup was to build his yacht with exclusive regard for speed.

Photos by Cribb, Southsea.

Note the tumble-home, giving easy sailing lines when heeled.

This line of thought reminds us of something that happened when we were watching the "Resolute" and "Vanitie" in their first trial race. A marine artist who was discussing the yachts said to the writer: "'Billy' Gardner is too much of an artist for his own good. 'Vanitie' is surely the sweetest thing that ever sat upon the water, but if Gardner had been willing to cut 5 feet off that beautiful tapering stern and another 5 feet off her long, keen bow, he would have saved sufficient weight on 'Vanitie' to gain several seconds of time in a 30-mile race." Nicholson has cut off the 10 feet of tapering grace and elegance; for his "Shamrock" is only 110 feet on deck, as compared with the 120 feet of the "Vanitie." Further evidence of weight-saving is seen in the considerable "tumble-home" of "Shamrock." She is broadest at the waterline, say about 23 feet, and cannot be more than about 20 feet in breadth at the deck. This means an additional saving in weight, because of the shorter deck beams and the reduced area of deck surface. True, this weight which is saved in the deck and put into the lead bulb is gained at some expense of beam; but as a compensation for this there is the fact that, when the yacht is heeled until her rail is awash, she is sailing upon easier lines.

Nicholson appears to have been willing to disregard the quarter-beam penalty, believing that the fuller waterlines, forward and aft, will give a sail-carrying capacity which will more than compensate for the penalties imposed. Judging from the photographs, the form of "Shamrock" appears to be a compromise between "Shamrock III" and "Reliance."

The construction of the yacht is very light, consisting of web framing, overlaid by a skin made up of three thicknesses of planking. The two skins next the framing are laid diagonally to give longitudinal stiffness, the outer layer being laid horizontally. The deck is exceedingly light, consisting of several layers of birch veneer, totaling less than an inch in thickness. A peculiarity in the outboard profile of the yacht, due to the persistent effort to save weight, is the fact that the sheer line drops somewhat, from amidships toward the bow—a change which will result in a not inconsiderable saving of weight in the forward portion of the hull.

The sail plan of "Shamrock IV" is similar to that of our own "Defiance." The mast is set far forward and the yacht carries a single head sail, the foot of which is laced to a boom, as in the case of "Resolute." The mast is so far forward,

(Concluded on page 493.)

Trial Races of the Cup Defenders

Promise of a Close Contest Between the Defending Yachts for First Position

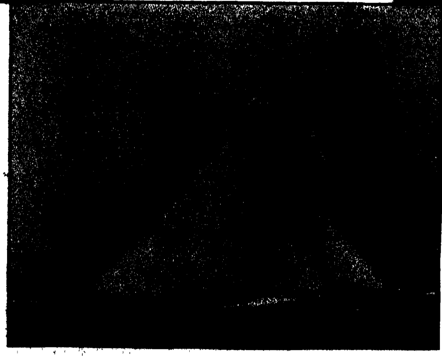
Photographs Copyright 1914 by Edwin Levick

WITH three yachts available for the defense of the "America's" Cup, the Cup Committee is going to make sure there is no mistake about the selection of the absolutely best of the three to meet the challenging vessel. No less than thirty-five contests will be held before a final choice is made. Of these, including those which have already taken place, twelve will be held in Long Island Sound, eleven will be sailed off Newport; three will be sailed on June 10th, 11th, and 12th off Sandy Hook; and during the New York Yacht Club's cruise in August, there will be a week of cup trials These races will provide an opportunity for the Cup Committee to observe the three defending yachts under all possible conditions of weather, from drifting matches to those sailed in a stiff blow

The first meeting of the yachts took place on June 2d over a triangular course off Great Captain Island, Long Island Sound. The "Defiance" was absent, for the reason that she was at City Island having a very considerable reduction made in her sail plan. In her preliminary tests the "Defiance" proved to be unable to carry her towering rig, heeling down under a breeze of moderate strength until her lee rail was far under water. Her mast is being shortened about nine feet, two feet are being taken off the main boom and something from the gaff, and it is hoped that with these changes the boat will be better in hand. We are not surprised that these defects developed. A reference to the plans which we published of the yachts on May 2d will show that the center of gravity of her lead is high relatively to the other two yachts. Furthermore, her keel is much shorter; in fact, in this respect she reminds one somewhat of "Independence," and, like "Independence," she has proved to be a difficult boat to hold on a true course. It is sincerely to be hoped that, after the changes are made, the "Defiance" will find herself, and that her owners will have the gratification of seeing her make a close fight for first honors with the other two yachts.

The first meeting between "Resolute" and "Vanitie," which was witnessed by the writer, verified the predictions which we made in our article published in the issue of May 2d. Whenever the course lay to windward and the sheets were flattened in, the Herreshoff boat pulled away from "Vanitie," particularly when the wind lightened. As soon as sheets were eased, the "Vanitie," with her long, easy sailing lines, proved to be the faster boat. On the first day the wind was very fluky, and to the skill of "Vanitie's" skipper in what is known as 'wind hunting' must be attributed a large part of the handsome margin of 16 minutes and 48 seconds by which "Vanitie" won the race From this must be deducted 3¼ minutes, the time that the "Vanitie" had to allow to the smaller boat

In the second race, sailed June 3d, there was a good sailing breeze throughout the race, and neither boat was particularly favored Here again the "Resolute" showed her superiority in windward work, and "Vanitie" proved the faster on a reach The boats finished with only 11 seconds difference between them. "Resolute" got away 12 seconds ahead of "Vanitie" and finished 11 seconds ahead, which with her time allowance of 3¼ minutes gave her an advantage of about 3 minutes and 26 seconds over the Gardner boat The superior work of "Resolute" to windward was shown by the time at the first mark, which "Resolute" turned at 1:9 57 and "Vanitie" at 1:11:59, or 2 minutes



"Vanitie" with her lee rail awash.

and 2 seconds later. In the broad reach home, "Vanitie" showed her reaching ability by cutting down the lead of "Resolute" to 54 seconds only. Going to windward over the 7½ miles on the second round, the yachts were practically even, and in the last homestretch of reaching "Vanitie" gained 31 seconds on "Resolute."

In comparing the two yachts it must be borne in mind that "Resolute" had had about one month of tuning up. Her sails were well stretched and their set was perfection. "Vanitie," on the other hand, had been out for only two or three short sail-stretching spins, and it was evident that her sails were in no such condition as those of "Resolute." As the various races take place, each will steadily improve, particularly in windward work. At the present writing, it looks as though "Vanitie" might be able, when she has thoroughly found herself, to save the 3¼-minute time allowance, with sufficient in hand to make her a winner by a slight margin. In any case, the races between these two yachts promise to be the most close and interesting that have ever occurred in the history of "America's" Cup defense.

An interesting feature in "Vanitie" is the fact that she is a model-basin yacht, several thousands of dollars having been spent in testing various models in the naval towing tank at Washington before the present form was decided upon. In this connection it is of interest to remember that by far the most successful yacht sent over from the other side, the "Shamrock II," was also a model tank yacht, Watson, her designer, having spent some nine months in experimental work in the model basin at the Denny yard, Scotland, in developing her form.

The New Wright Flexible Drive

THE new Wright flexible drive as adopted on the new aeroboats and military machines consists of an auxiliary shaft connected at one end to the motor by the shock-absorbing element and at the other end driving the propellers. On the flywheel of the engine there are fixed steel pins, and at the end of the auxiliary drive shaft there is a steel cone with similar pins attached to it. The pins on the flywheel are attached to the pins on the drive shaft cone by a number of shock absorbers. The transmission end of the shaft is supported by a bearing, while the other end of the auxiliary shaft merely rests on the crankshaft of the motor, free to rotate about it, but restrained and held in position by the shock absorbers. There is thus obtained a perfectly flexible unit, the power being transmitted through the shock absorbers. There are eight shock absorbers used in the drive for the six-cylinder Wright engine. Any variations or shocks in the rotation of the motor are taken up by the stretch of these shock absorbers. In a back fire, for example, the motor will stretch the shock absorbers almost a half revolution before effecting the transmission. The amount of spring that can be obtained by this device is very great. It takes up, without damage to the transmission or to the rest of the machine, the most severe vibrations of the engine, at the same time greatly easing up the strains on the engine itself. The additional weight of the drive on the new Wright aeroboat is only about 18 pounds.

In addition to reducing the shocks on the entire machine and greatly eliminating dangers of crystallization of steel parts, the introduction of the flexible drive permits of entire freedom in design with reference to the placing of the engines and propellers. In the case of the Wright aeroboat and the new Wright military machines, it has rendered exceedingly simple and practical the installation of the engine in front of the operators, motor-car fashion, with the propellers in the rear.

This combines the elements of safety due to placing the motor in front, the comfort and efficiency of the propellers at the rear, and (though the seats are back of the engine and slightly back of the edge of the planes) the view for observation is not in any way seriously restricted. The extreme comfort of flying in a machine of this type has been a revelation to those who have had the opportunity of taking trips on these new machines. There is a feeling of security in seeing the motor in front of one, and it is interesting to note that the noise does not seem to be as great as having the motor at one's back, or over one's head.

Important Regulation as to Guaranties Under the Pure Food Law

THE Secretary of the Treasury, of Agriculture, and of Commerce, acting under the authority vested in them by the Food and Drugs Act, looking to the joint making of regulations, on May 5th, 1914, directed that after May 1st, 1915, the regulation No. 9 of the Rules and Regulations under the Food and Drugs Act should be amended in several respects, particularly to the effect that hereafter, that is to say, after May 1st, 1915 no guaranty in any form shall be filed with and no serial number shall hereafter be given to any guaranty by the Secretary of Agriculture, and that all guaranties now on file with the Secretary of Agriculture shall be stricken from the files, and the serial numbers assigned to such guaranties shall be canceled, and that the use on the label or package of any food or drug of any serial number required to be canceled as above is prohibited. This regulation when once effective will materially change the manner of marking merchantable matter coming under the Food and Drugs Act.

The Fallacy of the Double Dirigible Balloon

By R. H. Upson

DOUBLE or multiple balloons have always been an attractive field for experiment, and it is unfortunate for this reason that they have so little practical value. Several balloons of this type have been built, notably that of M. Rose which attracted considerable attention a few years ago, but as far as I can discover, it never made any respectable flights. For all that, there is nothing impossible about such a balloon, but it would be comparatively inefficient, and there seems no more real occasion for one just now than a double boat or catamaran. The latter is sometimes made for a very special reason; so might a double balloon, but it would have to be a very good reason to overcome its many objectionable features.

The principal objections all depend on the following proposition.

If the volume of a single solid be divided up among two or more similar solids there will be more surface in proportion to the volume than before.

When applied to a dirigible balloon, this means that a double balloon of the same volume and gross lift will have more surface, more resistance, more leakage, less speed, will be more easily affected by temperature, will be harder and more expensive to make, and in ordinary cases will be heavier owing to the increased width of the car.

As a numerical example, let us see how much we can improve a medium sized dirigible of 375,000 cubic feet capacity and 200 horse-power by dividing it into two balloons, side by side, of the same length and gross volume. (The balloon is purposely assumed of comparatively low speed to give all the advantage possible to the proposed double construction.)

The longitudinal surface will be multiplied by 2. The weight of the gas bag will remain practically the same, but the weight of the car will be nearly doubled. Assuming the same horse-power and propeller efficiency, we get the following table of comparison:

	Original Dirigible	Double Balloon
Head Area	1,900 square feet	1,900 square feet
Longitudinal Area	34,000 square feet	46,700 square feet
Resistance of Gas Bags at 30 miles per hour	1,050 pounds	1,210 pounds
Resistance of Car at 30 miles per hour	250 pounds	400 pounds
Speed	30 miles per hour	28 miles per hour
Weight of Bag	4,600 pounds	4,600 pounds
Weight of Car	5,900 pounds	10,000 pounds
Surplus Lift	12,300 pounds	8,200 pounds

It can be seen that we have hurt the balloon in nearly every possible way and have gained practically nothing.

We could have a little more propeller area, but we need more with an increased resistance to keep the same efficiency. There would be more room to attach aeroplane surfaces, but we could attach all we would want to use to the original car without sacrificing so much.

It could turn in a little sharper circle, but that is hardly an advantage, especially as it could be effected, if desired, by merely increasing the rudder surface.

One of the objects of making a balloon in this form is frequently to give proper support to a very large aeroplane surface covering the whole bottom of the balloon. Going back to our assumed double balloon, a surface could easily be attached to the bottom which would be 200 feet long by 40 feet wide, or 8,000 square feet. As a Wright aeroplane of 400 square feet lifts about 700 pounds at the same speed, one might think that this surface would give a lift of 14,000 pounds, but such is far from the case. There are several things which very much lower its efficiency. It is flat, it is long in the direction of motion, and the big balloons interfere with the free flow of air around it. Neglecting the last consideration, the reaction on such a surface is expressed fairly well by Newton's old formula which, for an angle of 10 degrees, gives a lift of 680 pounds, or actually less than the small but properly proportioned aeroplane, at about the same angle.

It might be said that this formula assumes an infinitely long plane, but all things considered, the result is probably not far from correct. If we take 800 pounds as a fair estimate, we get 0.1 pound per square foot of surface, not even enough to lift its own weight. This almost inconceivable difference is not only a theoretical deduction, but it has plenty of experimental proof.

The following argument is sometimes used for a flat or multiple balloon: "An aeroplane has a very small resistance in a direction perpendicular to its course; hence it is not very easily blown out of its course by a side wind; but the ordinary dirigible is at the mercy of the winds on account of its large side area. This side resistance could be very much cut down by multiplying the balloons laterally."

A little thought will at once show that this argument is entirely fallacious. I won't try to prove it here except by saying that if such an argument could be proven sound, then perpetual motion is a *realized fact*. Here is the proposition, and I can't state it too strongly.

Given a wind of uniform velocity and direction, and an airship of any kind suspended in and by the air and using the air for propulsion. Then no matter how hard the wind blows or what the form of the airship is, it can go *through the air* (not over the ground) in no other direction and at no other speed than that determined by its own power. That is, in a given wind of uniform velocity the question of dirigibility is merely one of speed, *and absolutely nothing else.*

The numerous gusts and eddies in an actual wind affect the stability of an aeroplane very seriously but do not materially affect its direction of motion. With a dirigible, the effect of gusts may be totally disregarded for most purposes, and the problem of resultant speed becomes merely one of relative motion like a boat in a moving stream. To a person in free flight there can be no wind from the side except in the nature of sudden gusts.

A low side resistance might seem to be of considerable value when using a drag rope, water brake, etc., and more especially to lower the wind pressure when moored to the ground; but here again the result is out of all proportion to the cost of attaining it.

We now come to a possible use for the double balloon which does not apply to present sizes, but which is nevertheless real, and would be well worth investigating for extremely large sizes.

Consider the fabric above the suspension as made up of two parts or layers, one to resist internal compression, and the balance to carry the weight. Call these *A* and *B*. For equal strength and speed, the weight of *A* per square foot will vary just a little more than as the diameter of the balloon, so that for similar balloons the total weight of *A* is nearly proportional to the total volume or lift. The case of *B* is different. It has to sustain a weight, per foot of length, which is very nearly proportional to the area of the section or to the square of the diameter. Hence its weight per square foot will vary as the square of the linear dimensions and its total weight as the fourth power of the dimensions (for similar balloons). As the lift only increases as the cube, a point will evidently be reached when the weight of the gas bag will be excessive compared to the lift. It then becomes necessary to change the design so as to shorten the length of the fabric passing over the balloon.

This could be easily done by making the balloon double. But it would not be of advantage until the balloon was well over 1,000 feet long; and even then, it is probable that a better solution would be found in the rigid type as developed by Count Zeppelin.

Inventor of the Tabulator Typewriter

SOME time ago it was stated in the SCIENTIFIC AMERICAN that H. S. McCormack was the inventor of the tabulator typewriter. We are indebted to the Underwood Typewriter Company for copies of the decisions of both the lower and higher United States courts in the State of New York, in which decision it is held that Josiah B. Guthright was the first inventor of the typewriter tabulator.

The Death of Dr. Von Mauser

DR. PAUL VON MAUSER, inventor of the well-known rifle that bears his name, died in Berlin on May 29th at the age of 76. He began life as an humble gunsmith. He is said to have been financed by an American named Norris. His rifle was later adopted by the German army and several European armies.

The Current Supplement

IN this week's issue, No. 2006, of the SUPPLEMENT, Dr. E. F. Roeber's presidential address before the American Electrochemical Society is published. Its subject is "Some Economic and Æsthetic Aspects of Electrochemistry."—Prof. Kollmann shows how facial features are reconstructed with scientific accuracy from a human skull.—H. O. Swoboda writes on electric safety lamps for miners.—Dr. Glasebrook's paper on the development of the aeroplane is concluded in this issue.—E. Marriage, in an article illustrated with microphotographs, writes on the difficulties of detecting adulterations in fruit preserves.—Frank C. Perkins describes several types of electric cold saws.—Dr. Eccles's article on recent patents in radiotelegraphy and radiotelephony is concluded in this issue.

The Life Story of an Atom

By John W. N. Sullivan

THERE has always been something paradoxical about the notion of an atom. When we are told that matter is built up of a number of tiny little particles, which are themselves incapable of division, we grow perplexed. However small the ultimate particles of matter may be, they must have a certain size; and that being so, it is not at all clear why they cannot themselves be subdivided to an indefinite extent. As a philosophic theory, the atomic idea is most unsatisfactory. It is only when it is considered merely as a useful working hypothesis in scientific investigation that it has any value. Atoms are indivisible in the sense that an atom of any element is the smallest part of that element which takes part in any chemical reaction. Provided that we regard an atom in this light, it is a perfectly legitimate conception.

Lucretius, the old Latin poet, held an atomic theory of the universe, a theory which he enshrined in immortal verse. And although, philosophically considered, an atomic theory plunges us into difficulties, yet our imagination is equally baffled if we try to do without it. If we try to regard matter as perfectly continuous, i. e., as capable of infinite subdivision, we shall find it quite impossible. This dilemma has led to all sorts of queer theories, but we shall see that the modern scientific theory of matter is a peculiar compound of both views.

The modern theory is the outcome of the startling discovery that the atom is by no means indivisible, even in practice. It has been shown experimentally that the old chemical atom is built up of a number of much smaller particles, and we shall see that there is good reason to believe that these very small particles are really indivisible, in the sense that if they were divided they would also be annihilated in the process. These very small particles are called electrons, and they were first discovered in the course of experiments made on the electric discharge in vacuum tubes. It is well known that if we try to make a current pass between two conductors which are separated by an air space we have to use a very high potential and the current passes in the form of a spark. If, however, we put our two conductors in a tube from which the air has been almost completely exhausted, we get some very extraordinary results. Close to one of the conductors we get a blue glow, succeeded by a dark space, which in turn is succeeded by another luminous region. But besides these appearances, and crossing over them as though regardless of their presence, is a shaft of bluish light, which proceeds in straight lines from the surface of the conductor. If the conductor has a concave shape this shaft of light may be concentrated to a focus; and if a piece of platinum be placed at the focus it will be rendered incandescent. When the stream strikes the walls of the vessel or a solid obstacle within it, we get a phosphorescent glow, the color of which depends upon the material composing the vessel or obstacle. Clearly defined shadows are cast on the wall of the tube by any solid object which is interposed in the path of the stream. This stream or shaft of light may be deflected by magnets or electrified bodies brought into its neighborhood, and from the way in which these deflections occur, we are led to infer that the stream consists of a number of very small particles charged with negative electricity, moving at the rate of several thousands of miles a second. When these particles are abruptly stopped by collision with the walls of the containing vessel, they throw the surrounding ether into a state of disturbance, which manifests itself as rays of very short wave length—the famous X-rays with which everybody is now familiar, and which have such numerous applications in surgery and medical science.

The members of this stream of negatively electrified particles are identical in their properties, and they are called negative electrons. The mass of a negative electron has been found to be about 1/1700 of that of the lightest of all known atoms—the hydrogen atom. The conductor from which these negative electrons are shot off is called the negative electrode. If we perforate it streamers appear behind it, which consist of positively electrified particles, which are much larger than the members of the negative stream and also move at much slower velocities. Not only do the negative electrons set up disturbances in the ether when they are stopped by collision, but also when any change occurs in their velocities. If we merely change the direction in which an electron is moving, without altering the speed at which it moves, ether disturbances are set up, and energy is radiated away from the electron into external space. So that an electron rotating at a uniform speed in a circle is continually radiating energy, since its velocity is continually changing in direction. We shall see that this fact has an intimate bearing on the phenomena of radio-activity.

The most interesting feature about these negative electrons, and one which has transformed all our ordinary notions of matter, comes to light when we investigate the relation between the mass of an electron and its electric charge. It was shown by Sir J. J. Thomson that when a body is charged with electricity, its apparent mass is increased. This increase in mass depends not only on the magnitude of the electric charge, but also on the velocity with which the body is moving. Now the electric charge on an electron has been measured, and likewise its velocity, so that we are in a position to calculate what part of its apparent mass depends on its electric charge. When this extra mass is compared with the actual mass of an electron measured experimentally, we find that the two results are equal: in other words, the *whole* mass of an electron is due to its electric charge.

This result changes our whole concept of matter, for all matter is regarded as built up of electrons, and the mass of an electron is purely electromagnetic. The electron itself then, is not matter as we know it. We may gain some idea of the modern idea of the constitution of matter, by considering the smoke rings that some tobacco smokers are able to produce. A smoke ring is produced by setting part of the air in a particular kind of motion, a motion at once of rotation and translation, which then travels through the air as if it were a separate object. In the case of a smoke ring the little particles of smoke caught up in the air travel with it and enable us to trace its progress. We have set up a local modification of the air, which then takes on a more or less permanent existence and travels through the air as if it were some solid body. If the air were continuous and frictionless, the smoke ring would last forever, and could, in conjunction with other smoke rings, build up systems which would manifest the properties of material bodies.

Now a continuous and frictionless medium does exist, to wit, the ether. The ether permeates all space and is the universal carrier of energy, whether in the form of X-rays, light rays, heat rays, or rays of electricity. An electron, then, is regarded as some modification of part of this universal medium; it is entirely composed of ether, and is yet different from the ether, much as a smoke ring is composed of air and yet travels through it as an independent body. So that the old philosophic puzzle as to the atomic constitution or continuity of matter here receives an answer which embraces both solutions. Matter is continuous, since it is one with the ether; and matter is atomic, since it is built up of small particles which are separate from one another.

The atoms of matter are built up out of electrons much as our solar system is built up out of planets. In each case there is a central body: in the case of the solar system it is the sun and in the case of the atom it is a change of positive electricity. Circulating round this central change are a number of negative electrons, the whole system constituting an atom of matter. By a consideration of the different systems which can be built up in this way we can account for many of the properties manifested by the chemical elements. But in regarding the atom as built up in this way there is one fact which must strike us as of unusual significance. On this theory, *matter is not stable*. We have already pointed out that rotating electrons radiate energy, and here we consider an atom as built up of a system of rotating electrons. So that an atom is not a stable affair. Energy cannot be radiated indefinitely without a fundamental transformation of some kind occurring. We should expect the atom to break up eventually into some simpler form.

The phenomena of radio-activity show us that this is precisely what does occur. In an atom of radium we have a system which is in process of disintegration. The radium atom is breaking up and ceasing to exist as radium. Elements of less atomic weight, the results of its destruction, form in its place. But they also, although more stable, are not permanently stable. They, too, must break up and disappear, to give place to still simpler elements. This process cannot cease till the atom is resolved into its constituent electrons, but side by side with this disintegration of matter we have a synthesis, of which we have the clearest evidence in the stars. The older and cooler stars contain more complicated chemical elements than the hotter and younger stars, and the conclusion is irresistible that we are in the presence of a gigantic evolution of matter from its primitive source in the universal ether Side by side with death we have birth, and the universe moves through ceaseless cycles from decay to a fresh renewing.

The Largest Insects in the World are described by O. W. Barrett in the *Philippine Agricultural Review*. The largest known winged orthopter is a species of phasmid, or walking-stick (*Palophus Titan* Sjöstedt) recently discovered in Nyassaland. Its body is 10 1/3 inches long. Borneo boasts a wingless phasmid (*Phobecticus Kirbyi* Redt.) 13 inches long. This is the largest living insect, but was surpassed by a dragon-fly-like insect (*Meganeura Monyi* Brongn.), with wing expanse of 25 inches and a body 14 inches long, which flourished in France in the Carboniferous period.

The Foucault Experiment

To the Editor of the SCIENTIFIC AMERICAN:

In the issue of February 14th, 1914, of your valued paper, you publish an interesting article, "Watching the World Revolve," of Foucault's celebrated demonstration in the Pantheon, in Paris, in 1851.

This experiment was repeated for the second time in the Spring of 1857, in the choir of the cathedral of Lausanne, by Prof Louis Dufour, of the academy of that city.

As a young student I was witness of said experiment, which was then repeated several times before a large number of visitors.

The E. J. C. Motor

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of May 2nd I was very pleased to see an article regarding my aviation motor, for which I wish to thank you.

I would, however, like you to correct a very important mistake which your correspondent has made in describing my motor, and which entirely destroys all the advantages that I claim for it. Your correspondent describes the motor as having a differential to regulate the speed of the two propellers. We claim just the opposite, that is to say, that we have no gears at all in the motor itself. There already exists a motor on the principle described by your correspondent, and it may mislead the interested parties the error published in your article. If my motor had a differential to regulate the speed of the propellers, it would not only not be any better than all the other aviation motors, but it would be much worse. My claim is that my motor will outlast all the existing motors of to-day, as it rotates absolutely free on its axle, which is mounted on ball bearings.

My motor is now running perfectly and flying every day at Chateaufort. We are waiting the delivery of a Caudron biplane, made under special design to hold enough gasoline for a twenty-four hour flight, with which we expect to prove that our motor is the best existing to-day.

E. J. CONILL.

The Coast and Geodetic Survey Tide-predicting Machine

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of May 30th, 1914, Mr. Fischer attempts to befog the public mind in reference to the facts contained in my note (appearing in your issue for May 2nd) by making the following statement

"The officials of that bureau are thoroughly familiar with its development from its first inception, prior to 1890 (the year in which Dr. Harris entered the service), to its final completion."

If Mr. Fischer can furnish any reliable evidence that the general scheme which characterizes the new machine and distinguishes it from other machines existed in any sense prior to my conception of it in the early nineties, he will have rendered a service to those who may be interested in the historical development of these appliances. I have no knowledge that such plan or scheme had been conceived at some earlier date, either here or elsewhere; nor have I any reason for believing that, subsequent to the construction of the Ferrel machine in the early eighties and prior to the time when the general plan of the new machine first occurred to me, the Survey had ever considered or recommended the construction or purchase of any tide-predicting machine other than some machine of the Thomson type.

Mr. Fischer's *Engineering News* article, and to which he refers, was apparently written largely in the attempt to minimize or ignore my claim as the originator of the machine. Moreover, the article contains statements which cannot be successfully defended.

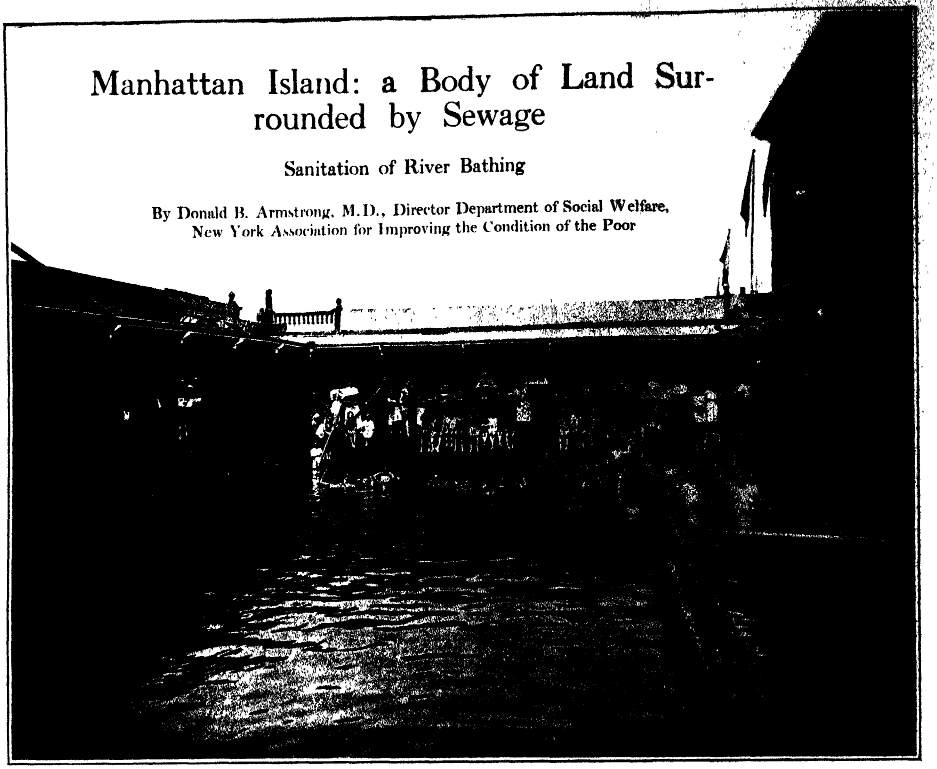
Washington, D. C. R. A. HARRIS.

The 72-inch Reflecting Telescope now under construction for the Canadian government, a description of which was recently published in these columns, is to be located on Little Saanich Mountain, near Victoria, B. C. This site was chosen after prolonged investigation of atmospheric conditions in different parts of the Dominion, and despite the fact that its selection entails much additional expense for the purchase of land, the construction of a road, and other preliminaries, as compared with other sites that were under consideration.

Manhattan Island: a Body of Land Surrounded by Sewage

Sanitation of River Bathing

By Donald B. Armstrong, M.D., Director Department of Social Welfare,
New York Association for Improving the Condition of the Poor



A typical floating bath. Coarse screens keep out the solid portion of the sewage, but the water is none the less contaminated, and, therefore, a menace to health.

THE majority of people have reached the point where they prefer their milk undiluted with typhoid-contaminated human excrement. This is, of course, partly a matter of decency, but largely a matter of health. Somewhat in contrast to this, it is found that most cities make large expenditures for street sprinkling, so that the food to be eaten may not be covered with a dusting of granulated horse manure. This is placed in contrast to the first proposition because, while there is an appreciable health factor, the chief justification of our effort in this field is based on decency. Most of our health or pseudo-health activities are founded on decency or health, or both. Rarely a problem is met where the two motive forces are not almost equally intermingled. Such would seem to be the case in the question of bathing in semi-sewage. It has been said that "Manhattan Island is a body of land surrounded by sewage." This is scarcely an exaggeration, for the waters adjacent to Manhattan, affected as they are by tidal currents, preventing a continuous and free flowage, receive about 499,000,000 gallons of sewage per day. This excrementitious material is inevitably infected and must remain, for a time at least, infectious. At certain times there is not a slip in the North or East River in which it is impossible to see human excrement. It was found necessary in the municipal floating baths, constructed with slats separated so as to permit the free entrance and exit of river water into the bathing tank, to nail additional slats over the openings, narrowing the spaces, so that the larger and, consequently, more objectionable particles of sewage did not enter. At the open beaches in the North River it is necessary to screen the river water as it flows down from the adjacent sewer by the bathing establishment so as to remove the unesthetic sludge. Screening, while admittedly necessary in this situation, is not considered a final method of treatment in sewage disposal, and obviously would be particularly objectionable as such if we are using the sewage for drinking purposes, and that is practically the situation when it is used for bathing. It is impossible to maintain a bath on the shores of Manhattan Island not adjacent to a sewer exit, for there are 140 sewers emptying into the rivers from that borough alone. Hundreds of thousands of people use this medium for cleansing and recreation purposes every Summer. It is equally dangerous and indecent. Its sanitation or elimination is essential for establishing public decency and for insuring public health in New York city.

At the present time there are three main types of bathing in New York harbor.

1. Unregulated Bathing.

This promiscuous and surreptitious bathing is from the piers and bulkheads at the foot of many of the streets. This is forbidden, though the enforcement of the regulation is practically impossible without a more thorough policing of the waterfront.

2. Beach Bathing.

There are several open beaches in New York Harbor, north of the Narrows and south of Spuyten Duyvil and the Bronx Kills, notably those adjacent to Washington Heights on the upper North River. Nothing is done, and of course nothing can be done at these places short of a radical change in our method of sewage disposal, to sanitate the water used in these baths.

3. The Floating Baths.

These are both public and private, and are situated in the North River and the East River and at the Battery, in the Boroughs of Manhattan and Kings. The baths of this type maintained by the city alone were used by 1,818,721 bathers in the year 1911. Yearly in New York there are about 550 deaths from typhoid fever, which means an incidence from this disease of about 5,000 cases. How much of this infection is a result of the short-circuit of contaminated excrement from individual to individual through river bathing it is impossible to say. It would seem safe and reasonable to assume, however, that the factor was not a negligible one.

What are we to do with these various forms of bathing? All authorities are agreed that the water should not be used unless in some way treated and rendered both safe and decent. Those who have reached this conclusion are agreed, also, that unregulated promiscuous bathing, as well as unprotected beach bathing, must be discontinued, for at the present time it is impossible to treat the water properly in these instances. What can be done with the floating baths? The results of bacteriological studies carried on by the Bureau of Public Health and Hygiene of the New York Association for Improving the Condition of the Poor indicate that radical treatment is necessary.

The counts practically represented the condition of the river water as well as of the water in the baths. The inconsistency of permitting bathing in this highly-polluted water without any attempt at purification and at the same time insisting on filtration and disinfection of Croton water for indoor pools is obvious. At the present time Croton water rarely contains over 100 bacteria per cubic centimeter, and with great consistency Colon bacilli are *not* found in 10 cubic centimeters. This water is filtered and disinfected when it is used in indoor pools. In contrast to this, the floating baths have encouraged bathing in semi-sewage where the bacteria are frequently as high as 3,000,000 per cubic centimeter, and where Colon bacilli, undoubtedly of human fæcal origin in this location, are found frequently in quantities as small as 1/1000 cubic centimeter.

With the floating bath it is possible to do one of three things, and these possible solutions will be discussed under the following headings:

1. Discontinuance.

This would seem to be the most logical and economic method. Floating baths as originally constructed cost the city $12,000 or $15,000 apiece. They were simply floating basins, having on them dressing-rooms and toilet facilities. They do, undoubtedly, take advantage of the tendency of the boy to go in swimming in the Summer time. At the same time, when, as under present conditions, he is compelled to satisfy that desire by swimming in sewage, one concludes that a redirection of the same tendency is worth the expenditure of a great deal of energy and money. The floating baths are open on an average of about three months a year, while an indoor bath may be kept open, and ordinarily is, the year round. The increased effective-

[illegible] of the indoor bath, because of the fact that it is open the year round, is a factor worthy of serious consideration. It would require $30,000 as the initial cost of providing a single model floating bath with filtration and disinfection, the operating expenses of which would undoubtedly be greater than those from which the above figures were taken, and the efficient and safe handling of which would be exceedingly doubtful under the best of circumstances. It may be said that for three times that amount a reasonably large indoor bath, equipped with showers and a pool, could be constructed. The West Sixtieth Street bath, containing 69 showers, 1 tub, and 1 pool, cost $126,550 in 1906. If the plan were, as has been previously advocated, to have smaller baths, with fewer units, at more frequent intervals, and if it were planned to have, eventually, these small baths at reasonably frequent intervals in the congested population centers near the water's edge, it might be reasonably supposed that the ideal bath for these purposes would be smaller than the West Sixtieth Street plant. It is probable that an equipment of 40 showers and a smaller pool would cost approximately $90,000. If the floating baths were entirely discontinued, and were replaced by small indoor baths at frequent intervals, there would undoubtedly have to be, for a time at least, some policing of the waterfront, to prevent the boys from going in bathing off the wharves. Positive measures of public bath advertising would help to accomplish this.

2. Reconstruction for Use of River Water.

In some experiments carried on last Summer in co-operation with the Department of Public Works, the Department of Social Welfare of the Association for Improving the Condition of the Poor had a tentative plan drawn up for an equipment that would meet this need to be attached to one of the present municipal floats. This was so devised as to permit the use of either fresh water from a street main or salt water from the river, disinfected with hypochlorite of lime and filtered. The present municipal floats were constructed in 1880 and have seen a good deal of wear and tear, so it is doubtful if they would stand much more service when subjected to remodeling with additional equipment. This is particularly true in view of the fact that additional equipment would have to include pumping apparatus. Here also enters in another objectionable item of expense, especially when it is to be of use for only three months of the year. It would seem that permanent all-year-round indoor pools were decidedly more advantageous and promising than river bathing under these conditions. It may be logical and desirable to turn to the river for our baths when we have found a way of discontinuing contamination of the river as a whole. The success of purifying the water piecemeal, so to speak, is extremely doubtful.

3. Reconstruction for Use of Fresh Water.

In co-operation with the municipal authorities, a tank of this kind was actually completed and put in use in September of last year. Croton water was used from a street main and was run into a float at the foot of East Fifth Street, being distributed by a number of inlet pipes placed at the bottom of the pool. The water was disinfected with hypochlorite and was run into the pool without filtration or refiltration in sufficiently large quantities to change the water in the pool at least once every day. With this plan there was no pumping expense, though there was a large waste of Croton water. The experiment was not a great success for several reasons, the chief one of which was the non-water-tight construction. Safety and decency can undoubtedly be secured by this method with a greater outlay, though the plant is useful for only a small part of the year, and it would seem that the money which must be spent on the additional equipment and reconstruction might be more effectively employed in increasing the capacity and the use of the all-year-round baths Recently the Board of Health of the city of New York approved a set of regulations regarding bathing in pools in or adjacent to New York city. These rules require water-tight construction, sanitary toilet facilities, shower facilities, etc. In view of the additional equipment which these requirements imply, it would seem that the first method discussed, that is, discontinuance, were the one to be advocated. With this should go, of course, positive constructive measures regarding the indoor pools. It is probable that very few private-bath owners can afford to make the changes necessary. Is it a rational municipal expenditure?

Four samples of Hudson River water from widely separated points.

Sewer discharging into Hudson River.

The chief justification for this municipal activity, in any event, is its educational value. At the present time the city has an excellent nucleus of cleanliness and health-promoting indoor pools. Those already in use are to be found at Rutgers Place, East Twenty third Street, and West Sixtieth Street. A new one is to be opened immediately at the Rivington Street bath, while three more pools, two at East Fifty fourth Street and one at West Twenty eighth Street, are under construction. Still another is planned at Carmine Street, and it is hoped that the municipality will see the necessity for the construction of a pool on the upper East Side, possibly in connection with the bath on East 109th Street. Besides these plunges the city has, at the present time, distributed in twelve public baths, 1,297 shower units and 80 tub units, the use of which, together with the pools, is entirely free. These indoor baths encourage cleanliness all the year round, while the river baths practically afford a series of swims during the Summer time. The floating bath is not nearly so apt to form a bath habit, for it must be discontinued in the Fall. The returns, in cleanliness and health, from an investment in indoor-all-year-round baths promises to be many times what might be the expected returns from the floating baths.

The Gordon Bennett Race

THE French Aero Club had some difficulty in deciding where this year's Gordon Bennett aeroplane event was to take place. On one hand, the municipality of Vichy proposed to organize the affair and to lay out the grounds, and on the other hand, M. Blériot offered the Buc grounds for the event. Opinion lay in favor of holding the event at Buc, for this year's rules require a circuit of 3 miles' length and 300 feet width, upon which an automobile can run at slow speed. Such a track costs much to lay out, but it can be done more easily on the Buc grounds, for these are already in good condition. Pilots, of course, prefer the track which lies near Paris and is among the aviation centers, and as regards the attendance of the public, the latter place is a much better one. Accordingly, after some discussion, it was decided to hold the cup event at the Buc grounds, and it will take place in September. It seems undecided as yet whether or not the United States will participate.

Variable Speed Transmission and Rotary Pump

A Hydraulic Motor Using Planetary Gears for Piston

FOR many years, particularly since the advent of the automobile, many efforts have been made to devise a simple variable speed transmission gearing. Such gearing is needed in an automobile to transmit power to the differential without the use of change gears, in battleships to elevate the guns and train the turrets; in machine tools to provide different speeds without shifting belts and gears As yet no strictly mechanical transmission gearing of this type has been commercially developed, but there are several hydraulic systems in use

Herewith we illustrate a new transmission gear of the hydraulic type, which, however, differs materially from previous gears and is decidedly original and ingenious. It is the invention of Mr. Herman Dock.

It works on the motor and a pump principle, the pump supplying fluid to the motor in volume controlable at the will of the operator, thus controlling the speed of the motor Motor and pump are similar in construction, and will be understood by referring to the sectional view, Fig. 1 Fixed to the casing of the motor is an internal gear *A*, which is of quadrilateral form Mounted on a shaft at the center of the casing is an elliptical gear *B*, while between the elliptical gear and the internal gear are six planetary gears, 1, 2, 3, etc. The design of the internal gear is such that when the elliptical gear is revolved, the planetary gears will mesh with both the internal and the elliptical gears at all points The planetary gears will, of course, travel in the direction of rotation of the elliptical gear, owing to their contact with the internal gear The planetary gears may be considered the pistons of the motor, while the spaces between them are the cylinders It will be noted that the space between planets 1 and 2 is much greater than that between planets 2 and 3 As the planets progress in the direction of the arrows the volume of the cylinder space between pistons 1 and 2 diminishes, while that between pistons 2 and 3 will grow larger. Hence, if this be considered a pump with inlet and exhaust ports, the first cylinder will be discharging through port *C*, while the second cylinder will be sucking through port *D*. Conversely, if the apparatus be used as a motor, fluid admitted through port *D* will cause the pistons to progress so as to increase the cylinder space between pistons 2 and 3 while at the same time the fluid in the cylinders between pistons 1 and 2 will be discharging through port *C*. It is interesting to note that while the elliptical gear advances 135 degrees, the cylinders advance only 45 degrees, and while there are only six cylinder spaces, the machine operates as if it had eight cylinders, and there are eight discharge and inlet ports.

Fig. 2 shows how the mechanism is employed as a variable speed transmission. It consists of two parts, namely, a motor and a pump. The pump consists of two units. The internal gear of the motor is indicated at A^1, and the elliptical gear at B^1, while the internal gears of the pump units are shown at A^2 and A^3, and the elliptical gears at B^2 and B^3, respectively. One of the pump units is adapted to deliver fluid through the other pump unit. The internal gears A^2 and A^3 are adjustable one with respect to the other under control of the lever *E*, which operates a bevel pinion *F* meshing with beveled teeth cut on the adjacent faces of the gears

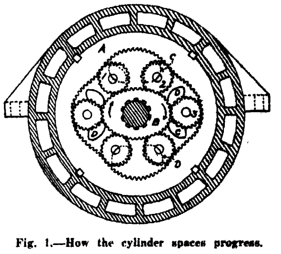

Fig. 1.—How the cylinder spaces progress.

Figs 3 and 4 show the results of adjusting one gear with respect to the other In the position shown in Fig. 3, one pump unit is indicated by full lines and the other by dotted lines, it will be seen that a cylinder of one pump member faces a discharging cylinder of the other, so that one takes in all the oil that the other discharges, and no fluid is delivered to the motor. When, however, the gears are moved to the position indicated in Fig. 4, the sucking cylinders of the two pump units pull together, and the discharging cylinders discharge together, consequently a maximum amount of fluid is delivered by the two pump units to the motor, and the latter is now driven at full speed. Any speed between maximum and zero may be obtained by relatively moving the two gears A^2 and A^3 between the extreme positions shown in Figs. 3 and 4.

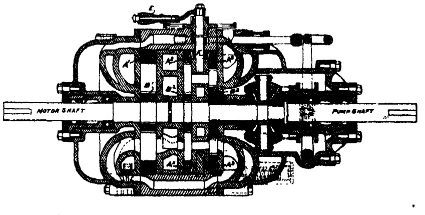

Fig. 2.—Longitudinal section of the variable speed gear.

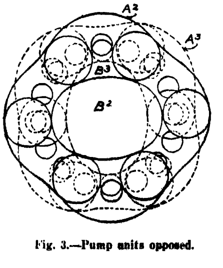

Fig. 3.—Pump units opposed.

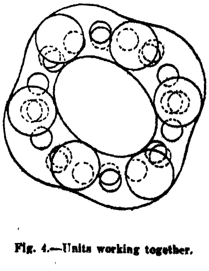

Fig. 4.—Units working together.

It will be noted that this is a true rotary in absolute mechanical as well as hydraulic balance, so that there is no pressure on any part that is not absolutely met with the exact pressure on the opposite side. In fact, if gears could be cut perfectly and would not wear, there would be no necessity for a bearing. Up to the present writing, no engineer in this country or Europe has been able to lay out the pitch line of the internal perfectly. It was found by the "cut and try" method and then master cutters were made.

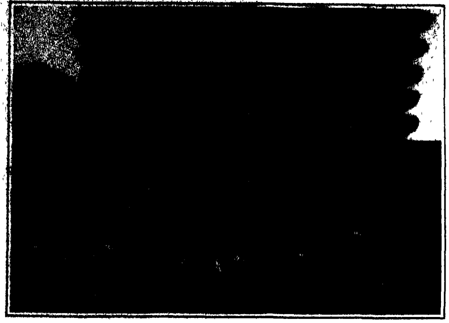
The accompanying photographs show a fire pump constructed on this planetary gear principle. Recently, on an endurance test of 100 hours, this pump, measuring only 9½ inches in diameter by 2⅛ inches in length, made 4,800,000 revolutions and delivered 1,100,000 gallons of water.

Counterfeit Weather Forecasts

ALTHOUGH the almanac weather prophet still plies his trade to-day, as he did hundreds of years ago when Justus Stöffler threw all Europe into a panic by announcing that certain planetary conjunctions would bring about a second deluge, it appears that there are legal snags upon which the modern prognosticator is in danger of running, if he happen to utter his predictions within the jurisdiction of the United States. Proceedings were recently brought in the United States court at Detroit against the publishers of a "Family Almanac" under a section of the Penal Code, which reads as follows: "Whoever shall knowingly issue or publish any counterfeit forecast or warning of weather conditions, falsely representing such forecast or warning to have been issued or published by the Weather Bureau, United States Signal Service, or other branch of the Government service, shall be fined not more than five hundred dollars, or imprisoned not more than ninety days, or both." On the title page of the publication in question appears the following statement: "Including a map of the United States and Uncle Sam's Weather Predictions." Needless to say, the predictions, which are made up for a year in advance, are not "Uncle Sam's." The publishers were found guilty and fined $100 for each of the three years during which the forecasts had been issued.

[illegible] Moving-picture Scenery

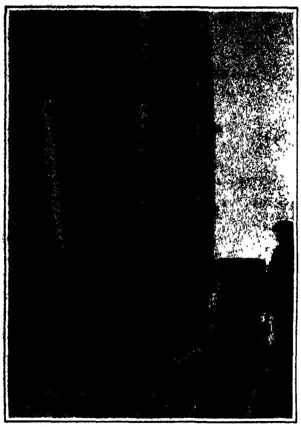
EXAGGERATION of the cost of moving-picture films is the rule rather than the exception, and so when we hear that a recent film has cost a quarter of a million dollars to produce, we are sure that the actual amount has been greatly overstated. Nevertheless, D'Annunzio's photo-play "Cabiria," it may readily be seen, involved an enormous expenditure. It rivals such plays as "Ben Hur" and "Quo Vadis," but differs from them chiefly in having been written particularly for the kinematograph. The author personally managed the staging of the play and, in order to have it as real as possible, the actors were engaged long before the final performance, in order that those who were to represent athletes could develop their muscles by gymnastic exercises, and those who were to represent bearded men could raise real beards, and thus avoid the usual wig and make-up. The story of the play belongs to the time of Hannibal and the scenes vividly portray the horrible religious rites of human sacrifice practised at Carthage, in the Temple of Moloch. Cabiria is a Roman girl stolen by Phœnician pirates and sold to the priest of Moloch, who is about to offer her as a sacrifice to the "God with the White-Hot Heart" when she is rescued. To stage the play, a most elaborate temple was built of plaster. The accompanying illustration represents the great gate of the Temple of Moloch. There are interior views of marble halls richly decorated and ornamented with representations of the sculpture of that time. *In addition to the scenes* at Carthage, there are views of Hannibal leading his army over the Alps, a Roman battle at Cirta with catapults, derricks, and all the machinery of ancient war. The pictures were taken in Italy, Sicily, Switzerland, Africa, and Spain.



Gate of the Temple of Moloch, constructed for a photo play.

Machine for Sawing Stone Walls

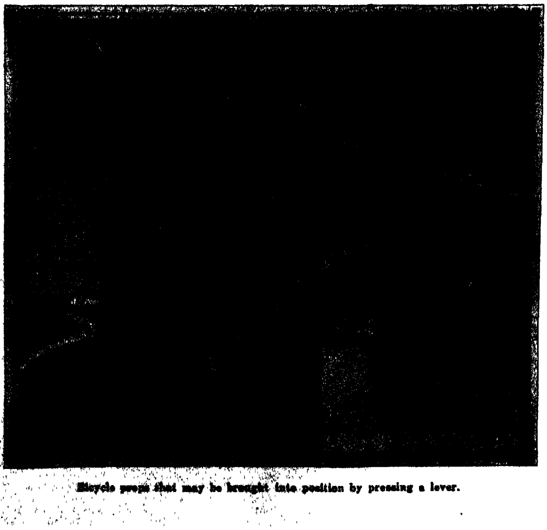
THE modern builder thoroughly appreciates the importance of waterproofing foundation walls to prevent dampness from creeping into them and injuring them. Accordingly, it is the custom to protect the foundation walls with a good coating of asphalt or the like. However, there are many buildings, particularly in the older countries, in which no such provision against the entrance of dampness and frost was made. In order to preserve these buildings, a method of insulating them against dampness has been devised by a German engineer. It consists in sawing a slot in the foundation wall just above the ground line and introducing in the slot asphalt-coated lead plates. A special machine has been designed to saw the masonry, producing a kerf about one inch wide. As the work is done progressively, the plates being introduced as the sawing proceeds, the stability of the building is not endangered. However, to prevent any possible accident, conical iron cramps are introduced in the saw kerf. After the introduction of the insulating plates the slots are closed with temporary wooden forms, and then they are grouted with liquid cement, which completely fills them and any gaps still left open. The cement adds to the insulation, and the wall is thus thoroughly protected against creeping of moisture from the ground upward. To dry out the walls over the insulating plates, a special stove is provided.



Sawing foundation walls to introduce waterproofing plates.

Bicycle Fitted With Side Props

THE convenience in having a device for making a bicycle stand still when it is stopped on the road will be at once appreciated, for it will come into use in numerous cases when the rider wishes to stop without dismounting from his machine. Our photographs show a bicycle in this position, it being held by a forked support at the rear, and the various details of the device are also noticed. The supporting device is of a most simple kind, and is at once brought into use by pressing on a lever. On the lower tube of the bicycle frame and next the rear wheel hub is clamped a bracket. This serves to hold a light steel rod on either side of the machine, which forms the support The rod is journaled in the bracket, but, being a bent shaft, its lower leg takes the two positions shown in Figs 1 and 2, when it is turned in its bearing. In the first position the leg projects to one side as a prop, while in the second position it is folded up against the side of the wheel. All the movement is controlled in an easy manner, by the use of a lever. Various means can be adopted for placing this lever, but the best one is shown in Fig. 3. On the handle rod is mounted the usual brake, seen on the left, and next to it is a lever of quite similar kind, but somewhat differently mounted, so that by pressing the lever we pull on a wire in quite the same way as for the brake. This wire works in the customary flexible tube, and it goes down along the frame to the bent upper end of the pivoted rod or leg which we mentioned above. A double wire allows of working both legs at the same time. A spring upon the collar or support keeps the legs held up in the inactive position, and when the lever throws them upon the ground, a suitable clamp or lock device keeps them there, so that the hand pressure need not be further applied It will be seen that the device could hardly be simpler or easier to operate When on the road, it will now be possible to stop for a moment in order to enjoy a view, or even to take photographs, and for this latter use it will be most useful in allowing time-exposures to be made, the bicycle serving as a tripod. In cities and when traveling upon crowded streets where the rider becomes blocked by vehicles, he is able to stand still until free to proceed, without being obliged to dismount, as so frequently happens



Bicycle props that may be brought into position by pressing a lever.

News from the "Karluk"

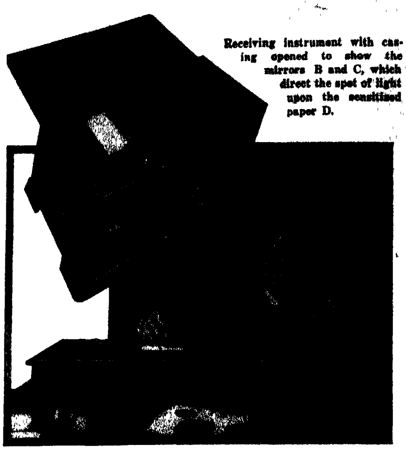
THE mystery which has enshrouded the fate of Vilhjálmur Stefánsson's ship "Karluk" since she drifted away from the Alaskan coast, September 22d, 1913, carrying with her about half the scientific staff of the Canadian Arctic Expedition, is now happily at an end. A dispatch from St Michael's, Alaska, announces the arrival at that place of the "Karluk's" sailing-master, Capt. Bartlett, with the news that the vessel was crushed by the ice and sank about sixty miles off Herald Island (northwest of Bering Strait) on January 11th. The ship's company escaped over the ice to Wrangel Island, from which point Bartlett sledged to the Siberian coast, where he fell in with the whaler "Herman," which carried him to St. Michael's As soon as navigation opens, the Canadian government will undoubtedly send a vessel to rescue the party marooned on Wrangel Island Much interest attaches to the course over which the "Karluk" drifted, as bearing upon the plans of Amundsen and others to approach the pole by drifting from a point north of Bering Strait The drift of the "Karluk" ended almost exactly where that of De Long's ship "Jeanette" began, in 1879, while the point at which the "Jeanette" sank was not very far from where the drift of Nansen's "Fram" began, in 1893 The combined routes of these three vessels thus give a general idea of the drift of the Arctic currents more than half way around the north polar basin. They are at once unfavorable to the plan of utilizing ocean currents as a means of reaching the pole, and favorable to the idea that extensive lands exist in the unexplored region of the Arctic Ocean News is now eagerly awaited of Stefánsson's proposed sledge journey northward from the Mackenzie delta and of MacMillan's northwest from Axel Heiberg Land; either of which may have resulted in the attainment of the lands in question.

Yellow Poplar, or tulip tree, the largest broadleaf tree in America, has been known to reach nearly two hundred feet in height and ten feet in diameter.

New Apparatus for Writing at a Distance

A VERY *ingenious apparatus* has just been introduced from Germany, which is designed to transmit writing, drawing, and the like over a telephone or telegraph line to an instrument which makes a perfect reproduction of the original. Telautographs have long been in use, but this apparatus differs from others in many important particulars The writing at the receiving end is done by a pencil of light which travels over a sensitized sheet of paper. The message is thus photographically reproduced, the sensitized paper being developed automatically, in the machine, in a few seconds' time

The scheme of the device is shown diagrammatically in Fig. 1 At the left is the transmitting station; the receiving station at the right The position of a point is determined by noting the length of its abscissa and of its ordinate, in relation to two axes, or, to borrow a geographical simile, by noting its latitude and longitude. It is therefore merely necessary to transmit the latitude and longitude to the receiving station in order to locate the same point on a sheet of paper at that place Accordingly, the pencil *P* is provided with means for *controlling two variable resistances* R^1 and R^2, respectively These, in turn, control delicate galvanometers G^1 and G^2, respectively, at the receiving station, each fitted with a tiny mirror As more or less resistance is thrown *into the circuit at* R^1, the mirror *B* of galvanometer G^1 is more or less deflected, and a beam of light from the lamp *A*, playing upon this mirror, has its reflection correspondingly deflected. The reflected beam is cast upon the mirror *C*, which is mounted to turn on an axis at right angles to that of mirror *B* Mirror *C* is deflected by variations in the resistance introduced at R^2, further modifying the direction of the beam reflected therefrom In other words, one of the mirrors determines the latitude of the point of light that falls upon the sensitized paper *D*, while the other controls its longitude Accordingly, as the pencil is moved over the paper at the transmitting station, the pencil of light at the receiving station must reproduce the same line, point for point, on the sensitized paper



Receiving instrument with casing opened to show the mirrors B and C, which direct the spot of light upon the sensitized paper D.

Transmitting a message with the photographic telautograph.

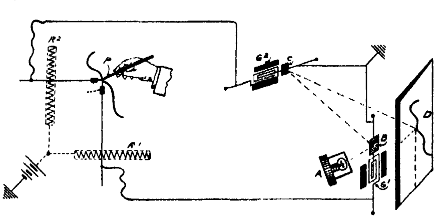


Fig. 1.—Diagram of the main circuits of the improved telautograph.

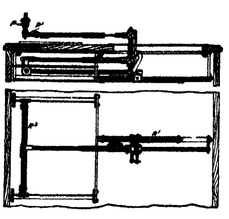

Fig. 2.—The transmitting pencil and resistance coils.

In the photograph of the receiving apparatus, the *place where the lamp is introduced is indicated by the* letter *A* The light from the lamp passes through a series of lenses and reflectors to the small mirror *B*, then to the mirror *C*, finally falling upon the sensitized paper at *D* The developing tank is shown at *E* After the message has been written, the machine automatically reels off the exposed paper, cuts it off, passes it through the developer, and issues it finally through the slot *F*, completely developed, fixed and dried, all in fifteen seconds

Detail views of the transmitting pencil and the variable resistance coils it controls are shown in Fig. 2, the upper view representing a side elevation, and the lower view a plan with the pencil and pencil arm broken away and the top of the casing removed The pencil is indicated at *P*, while at P^1 is an automatic contact which closes when the pencil is swung up to the writing position. The system is active only when the pencil is held in writing position and the lamp *A* glows only when the pencil is pressed down in contact with the paper. So the act of moving the pencil across the paper to dot an *i* or cross a *t* is not accompanied by a corresponding movement of the beam of light at the receiving station. As soon as the writer is through with his message, he lays down the pencil, whereupon contact P^1 is broken and the transmitting system becomes inactive, but the developing mechanism at the receiving station *begins to operate. Not until the message* has been developed can another message be written. If the operator should write a second message during the period of developing, no message would be transmitted. As soon as the receiving apparatus is ready for the second message, the fact is signaled by a disk on the transmitting apparatus, which shows white. Then the writer, on picking up his pencil and beginning to write, will hear a slight buzzing noise, indicating that the receiving apparatus is reproducing his message properly In other words, "he hears himself writing at the receiving station"

Referring again to Fig 2, the essential details of the transmitting station are clearly shown The pencil proper is supported upon an arm which passes through a slot in the top of the casing and is pivoted upon a carriage As the carriage slides back and forth in the slot, contact is made with the variable resistance coil R^1. As the arm swings upon its pivot, contact is made along the resistance coil R^2, which, it will be observed, *is mounted upon the wheels so that it can travel* toward or from the pivot, to adjust itself to the variable reach of the arm. One of the principal advantages of this apparatus is the fact that a message may be corrected; a word or a line may be inserted at any point after the message has been written, and not until the operator is satisfied that the writing is just as it should be, need he drop his pencil and have the photographic reproduction developed at the receiving end. This permits of transmitting drawings as well as ordinary writing. Instead of moving a pencil at the receiving end in frictional contact with the paper, there is the practically negligible inertia of two light mirrors. This permits of operating the device rapidly and accurately. The writing may be as small as desired, while the message received, being photographic, makes a fixed record that cannot be altered. The roll of photographic paper is sufficient to reproduce a hundred messages on sheets the size of a postal card. When the roll is nearly exhausted, warning is given by special marks on the last few sheets of paper, which will *serve to notify* an attendant that a new roll and a new stock of developer must be placed in the machine. Very little current is required to transmit a message over a mile or more.

Measuring Human Comfort

PROF. LEONARD HILL, F.R.S., and Mr. O. W. Griffiths have devised what they call a "caleometer," an instrument designed to measure the degree of comfort in a room, or a public hall, or a factory, in so far as that depends on the rate of cooling of the human body. The "coil," which is made of a wire having a temperature coefficient, forms one arm of a Wheatstone's bridge, the other arms of which are made of an alloy whose electrical resistance does not vary with the temperature. The bridge is balanced when the temperature of the "coil" is approximately that of the human body, the current being supplied from accumulators or from the main supply. Any tendency to variation of this temperature is checked by an automatic rheostat, worked by a relay, so as to diminish the current when the temperature rises, and *vice versa*. The indicator in the box shows at any instant the number of calories per minute supplied to the coil to keep its temperature constant. The coil can be placed at any distance from the indicator, to which any number of coils can be switched in succession, if necessary. Comfortable conditions are indicated by gentle oscillations of the pointer—about a mean value of 30 calories per minute. A low steady reading denotes monotony and oppressiveness; violent oscillations about a high mean value are evidence of excessive cooling by an unpleasant draught.

New Cathodic Glow Lamp

By Henri Marchand

IT has long been known that when a Geissler tube is subjected to an electric discharge, the negative electrode becomes hot, to a degree more or less marked, according to the intensity of the discharge and the current producing it. Based on this phenomenon, Dr. Greinacker, Zurich, has developed the new cathodic glow lamp here illustrated.

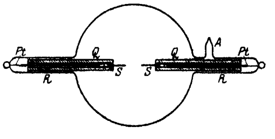

Fig. 1.—Construction of the cathodic lamp.

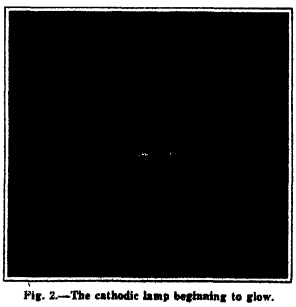

Fig. 2.—The cathodic lamp beginning to glow.

The lamp consists of a spherical glass bulb containing two electrodes (*SS*, Fig. 1), each consisting of a Nernst heater contained in a *quartz tube, and sealed in* by means of magnesia and pipe clay. Connecting wires of platinum are indicated at *Pt*, *Pt*. Air is drawn from the bulb, until the pressure is reduced to some millimeters of mercury

When the lamp is submitted to an alternating current of 1,000 volts, discharges take place, which soon heat the electrodes to a white-heat. With a current of, say, 0.1 ampère, the light furnished approximately equals that of a 50-candle-power lamp.

The voltage necessary for lighting the bulb will perhaps be diminished by using a suitable gas in the bulb, modifying conveniently the nature and pressure of the gas, etc. The appearance of the lamp when beginning to glow is shown in Fig. 2. The electrodes soon become incandescent.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Heating and Lighting.

EXTENSIBLE ELECTRIC LIGHT FIXTURE.—S. GARBRECHT, Idaho City, Idaho. The invention relates to suspended electric light fixtures employing a flexible suspending means, having a spring acted winding drum or barrel and a lazy-tongs composed of hollow members to receive the conductor wires. Novel means are provided for mounting and securing the winding drum, for guiding the extension elements and for preventing the lazy-tongs from swaying.

HEAT-INSULATED RECEPTACLE.—L. W. WHITE, Alzada, Montana. The receptacle combines the features of a sterilizing vessel and a fireless cooker. As a kettle it is provided with a lid adapted to be sealed for the purpose of retaining the vapors and flavors up to a certain desired high pressure. To form it into a fireless cooker, a special insulated bottom is provided which may readily be attached.

OIL BURNER.—G A. ULRICH, City of Mexico, Mexico. This oil burner is provided with a chamber for superheating steam before it comes in contact with the oil, to raise the temperature of the oil as it leaves the burner. The superheating is disposed over the mixing chamber and the steam from the superheating chamber is discharged below the outlet for the combustible mixture.

Household Utilities.

STOVE-KEY PLATE RATCHET-SUPPORT. J. E. LEONARD, 871 So. 19th St., Cedar Rapids, Iowa. The invention is an improvement in stove top plate ratchet supports and is designed to overcome objections to the ordinary support of this type, means being provided for supporting the plate with a variety of adjustments automatically operating by the movement of the plate. When the plate has been moved to an extreme position, it automatically disengages the ratchet mechanism and returns to normal position.

TABLE.—A. and L. RENZETTI, care of A. Alvino and Figle, 224 Lafayette St., New York. The invention relates to tables having adjustable tops whereby extra leaves may be added or removed when desired for increasing or decreasing the top of the table. The construction is such that the center of the top will always remain over the center of the pedestal of the table, thereby providing an even balance for the pedestal without the necessity of dividing the pedestal into parts.

PORTABLE AND FOLDABLE BATHTUB.—MRS. N. F. BONIFACE, 124 W. 44th St., New York, and SYMONA N BONIFACE, New York. This bathtub is designed for bathing babies, and is arranged to insure the utmost comfort of the baby while being bathed, to permit the attendant to fill and empty the tub conveniently, and to allow of turning the tub around, to facilitate the washing of the baby. The tub may readily be folded into a small bundle for storage or shipping purposes.

Of General Interest.

BALE BAND TIE.—I. M. THOMPSON, De Ridder, Louisiana. The invention provides a tie that may be applied quickly and removed readily. It is so formed that the band will hold the tie in place with only the slightest assistance from a spur or projection extending from the tie into the bale to which the tie is connected.

HANDLE ATTACHMENT. - W. H. JAYNE, 414 East 23rd St., New York, N. Y. Mr Jayne's invention relates to handles removably associated with a brush or similar article, the top of which article is also removable The object is to provide an additional handle attachment for brushes which may be used for different articles, provided with means for engaging a handle.

ANCHOR FOR SUBMARINES.—G. E. ELIA, Hotel de Crillon, Place de la Concorde, Paris, France. The invention provides a means for automatically locking the mooring winch when the anchor for a submarine mine reaches the desired position at the bottom of the sea, in order to render the length of the mooring cable independent of eventual displacement of the anchor under the influence of currents or other causes

BLANK BOOK.—S. R. CLARK, care of Spalding City Bank, Spalding, Neb. A combined register and ledger is provided by this invention which is arranged to afford convenient means for posting the sales in the ledger at the time they are entered upon the register. It comprises a set of leaves constituting the ledger and another set the register, the leaves being on a common writing surface in sight of the user.

THERAPEUTIC DEVICE.—C. E. MACARTHY, 228 West Chappel St., Griffin, Ga. The device comprises two levers pivoted together and arranged opposite each other, the inner sides of their longer arms being curved outwardly and a spiral spring interposed between the shorter arms of the jaws, which are extended in the same plane with their longer arms.

BURIAL STRUCTURE.—F. M. ROGERS, care of E. Nicholson, 78 Madison St., Seattle, Wash. This burial structure consists of a chapel in which burial services may be held, a receiving vault for temporarily receiving bodies, and thoroughly ventilated crypts as a final resting place for the bodies. In the floor of the chapel is an opening normally closed by an elevator platform on which the burial casket may be supported. The elevator provides access to the receiving vault underneath the chapel and the wings extending outwardly therefrom.

SUBMARINE MINE.—G. E. ELIA, Rome, Italy. An object of the invention is to provide a floating cable with mines suspended at each end, so that the cable when struck by the bow of a ship will be dragged along with the latter, so as to cause the mines on the ends of the cable to be drawn inwardly and into contact with opposite sides of the hull of the ship, when the mines will be exploded, with the effect of destroying the ship.

SMOKER'S POUCH—C. TWINING, 39 Leonard St., New York City, N. Y. The invention provides a smoker's pouch consisting of an outer envelope and an inner envelope, adapted to be disposed within the outer envelope, the latter being provided with means for holding a pipe, while the inner envelope constitutes a container for the tobacco.

DISPLAY RACKS FOR WINDOWS.—M. R. WOOD, 218 William Street, New York With the object of displaying merchandise to best advantage in show windows, the present invention consists of a bracket which may be secured to the casing of the window and a tubular arm with interlocking means for attaching the arm to the bracket, so that the arm will project therefrom at an acute angle.

METHOD OF COLLECTING PARTICLES PRESENT IN AN IONIZED MEDIUM.—W. W. STRONG, care of Scientific Instrument and Electrical Co., Mechanicsburg, Pa. The purpose of this invention is to provide a method of indicating the presence of smoke, dust, fumes, mist, or other particles present in flues and pipes as a means of checking the time when they are given off through the flues and the pipes and the relative amounts of the particles at such time. The invention is based upon the ionization of different media and proceeds upon the fact that particles present in an ionized medium may be collected through the use of an electric field.

APPARATUS FOR DRYING WASHED BIRDS, DOGS, AND OTHER ANIMALS.—R. G. FURLEY, address Day, Davies & Hunt, 321 High Holborn, London, W. C., England For the purpose of drying washed birds, dogs and other animals when intended for show purposes, in a quick and efficient manner, the present invention provides a cylinder divided into compartments by screen partitions, also an air-heating chamber, and an air-extractor, to draw the air through the cylinder.

PAPER CASE.—M. W. FASSMANN, P. O. Box 385, Fayetteville, Ark. This invention relates particularly to cases adapted and intended for holding rolls of paper, and particularly useful as a receptacle for mileage tickets, stamps, cigarette papers and other articles requiring the delivery from time to time of sheets or strips of paper.

FIRE ESCAPE—A. F. JONES, Nelson, Butte Co., Cal. This invention avoids marring buildings; provides a movable fire escape operable from a station accessible to an operator standing on the ground; provides means whereby the operative position of the escape is ascertainable without recourse to the escape directly; provides a structure arranged to prevent the parts thereof from becoming jammed or locked, and provides an escape for every window in the side of a house.

DEVICE FOR STACKING MAIL MATTER.—E. P. F. THOMPSON, Troy, Tex. This invention has reference to a device for use in stacking letters, circulars, newspapers, and other mail matter ready for tying in bundles. It is the design of the improvement to provide an article simple in construction, efficient in use, and capable *of being folded into small compass* when not required for use.

WIND SHIELD FOR MATCH BOXES.—F. C. LAMBERT, 242 E. Tremont Ave., Bronx, N. Y., N. Y. This wind shield is arranged for convenient attachment to match boxes, such, for instance, as contain safety matches in a drawer slidable in a casing, the wind shield when not in use folding upon the casing, and when extended for use permits of safely igniting a match for lighting a cigar or other article.

REMOVAL OF WATER FROM WET CARBONIZED PEAT.—N. TESTRUP, 6 Broad Street Place, and O SÖDERLUND, "Fairlawn," Clarence Road, Chapham Park, London, England. Externally and preferably slowly applied sustained pressure is used in removal of the water. This treatment preferably following a preliminary treatment in which pressure applied internally is used, i. e., pressure transmitted by the fluid itself. For this purpose, the wet material may be passed into a filter press and the water which is readily expressible therein removed in this way, a further quantity of water being then removed by subjecting the cake to pressure externally applied by a band or like press.

DENTAL CROWN REMOVER.—R. H. TAYLOR, Meeker, Colo. This inventor provides means for removing crowns or coverings from teeth by careful and painless application of force, to lift the cap or covering from the tooth to which it was applied; applies the force necessary for the removal of the crown or covering, at a distance from the tooth, for the convenience of the dentist; and provides a guide-plate from the tool having a peep-hole opening to guide the placement of the tool.

PIPE CAP.—S. N. MALTEENER, Canton, N Y. In this instance means are adapted to engage exteriorly with the bowl whereby the latter will not be defaced. The cap serves to prevent the lighted tobacco from being blown out of the bowl, especially when traveling or automobiling or in windy weather, although the improved cap will prevent extinguishing of the lighted tobacco in stormy weather and will serve to permit the proper draft and burning of the tobacco.

GUN SIGHT.—J. R. STEWART, 1111 A St., Tacoma, Wash. The inventor provides a sight of strong construction, and contrasting colors, whereby the sight can be used efficiently under different light conditions. He makes a perfect connection between the head and the support for the same, so that the vibration of the barrel caused by the discharge or any other rough, hard usage will not dislodge the head from the support.

Machines and Mechanical Devices.

SAW TENSIONING AND STRAIGHTENING MACHINE T W ROACH, Lyman, Wash. The invention relates to a machine for operating on circular and other saws, for performing the work known as rolling saws for tension, the machine being useful also for straightening a concave saw that has been forced over the saw collar The present invention provides an improvement on a saw tensioning and straightening machine previously patented by Mr. Roach

SAW GUIDE.—C. DEVERELL, Woodstock, Ore. The invention provides a device for supporting a cross-cut saw for making kerfs on the under side of the log with the saw in inverted position The construction is such as to possess more strength and simplicity than devices ordinarily employed, while eliminating devices which are liable to become broken or disarranged

GUIDE FOR SHARPENING BITS.—H. H. HOLMES, 527 Broadway, Council Bluffs, Iowa In order to hold planing bits in proper position while they are being sharpened, Mr. Holmes has invented a support having means for securing the bit thereto and a roller member associated with the support, forming means whereby the desired cutting angle of the bit is obtained when the plane is sharpened.

EXPENSE TABULATOR—E L. BROWN, care of Alfred R Rodway, 100 Hudson St, New York, N Y This invention refers to an expense tabulator which is intended primarily for use by traveling salesmen, whereby each expense as it is incurred can be easily and conveniently recorded on a strip of paper or other table contained in the device for daily or weekly records, there being a suitable printing mechanism that is adapted to be manipulated for printing on the tape various items of expense and amounts thereof.

INTERDECK DAVIT--R. TJADER, 51 E 42nd St, New York, N Y. The invention more definitely stated provides an easily controllable and safe means for launching life boats from various decks or between decks of a ship, whereby the confusion and loss of time incident to attempting to launch all the life-boats from the upper deck only are obviated

QUARTZ MILL—H F RANDALL, Tiffin, Ohio. An object of the invention is to provide a device having shoes disposed on a frame which may be oscillated in a horizontal plane A further object is to provide a device of this type, in which the horizontal oscillating frame may have a vertical movement, so as to ride over and crush larger pieces of the rock

CAN TOP FEEDER—C E FORRY, address H L. Guenther, care of Angelus Sanitary Can Machine Co, 310 North Ave 19, Los Angeles, Cal. The can tops are taken, one by one, from the bottom of a stack, a separator being provided *to prevent more than one from being* taken at a time, and then they are caught by the arms of a feed wheel, which carry them to the point of delivery.

Prime Movers and Their Accessories.

GEARING.—J M J NESS, care of Dakota Implement and Hardware Co, Maddock, N D The object of the present invention is to provide a device of a simple nature for converting the rotary motion of a windmill into reciprocating motion for working the pump rod The device is so designed that the gearing is enclosed in an oil reservoir, securing perfect lubrication.

OILER.—A. SCHOBL and A. E. BAUM, 42 Lafayette St., Waterloo, Iowa. Most of the windmills which have been in use for several years are so badly worn that it is difficult to connect with them any of the oilers now in use in such a manner as will insure an even and certain feed of the lubricant at all times This fault is removed by the present invention, which provides for a positive delivery of the lubricant under all conditions.

ENGINE STARTER—B G. PATTERSON, 1138 W. 14th St, Oklahoma, Okla This invention relates particularly to so-called "self starting" mechanism for automobile engines The engine shaft is spirally grooved at the forward end and carries a nut engaging these grooves. The driver operates a lever to draw the nut back along the shaft, causing the latter to rotate and turn the engine over, whereupon the nut is released by a ratchet mechanism.

Railways and Their Accessories.

RAILWAY SAFETY AND RECORDING DEVICE.—F. F. HUDSON, Memphis, Tenn. The invention comprises a train stopping mechanism, controlled by a closed track circuit, which will cause the stopping of a train by the application of brakes, and will also give warning in the cab of the engine to notify the engineer or fireman of impending danger. A recording device will record the obedience to or disobedience of signals by the engineer

CROSSING ARRANGEMENT FOR BLOCK SIGNAL SYSTEM.—MARK CONRAD and W G KELLY, Adrian Michigan An object of the present invention is to provide an arrangement for preventing a collision of trains at the crossing of two roads, either one or both of which are equipped with a block signaling system. Means are provided by which the circuits are closed through the operation of crossing signals so as to supply current for certain train stopping mechanism carried by the engine

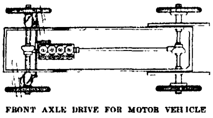
LOCOMOTIVE DRIFTING VALVE W J. SAXON, 92 West 30th Street, Paterson, N J The invention provides means for supplying the cylinder and steam chest of locomotives with saturated steam to avoid the drying and sudden cooling incident to the heat of the superheated steam and the vacuum formed by the movement of pistons Means are also provided for cushioning the pistons after the determination of the power steam supply in the cylinder.

Pertaining to Recreation.

APPARATUS FOR AQUATIC INSTRUCTION AND AMUSEMENT—C S JACOBSEN, 587 Pacific Street, Brooklyn, N Y A novel apparatus for instruction in the art of swimming is provided by this invention. It embodies a large swimming pool having a circular concentric platform adapted to travel on the sidewall or rim of the tank, the same being operated by a suitable motor and also provided with means for supporting persons in the water, the element of danger being thus entirely eliminated

Vehicles and Their Accessories.

FRONT AXLE DRIVE FOR MOTOR VEHICLE.—E R NICHOLS, 5716 Washington Ave, Chicago, Ill The present invention comprehends an improved means for driving a motor vehicle and especially a farm tractor through a shaft carried by the front or steering axle An improved universal joint is provided between the main part of the front axle and the spindle end so as to increase the pulling power and enable the tractor to turn short Irregular motion of a universal joint on one side is neutralized by that on the other, so that motion of the tractor is uniform



FRONT AXLE DRIVE FOR MOTOR VEHICLE

EMERGENCY AXLE—C P. SNYDER, 69 Dowel Street, Slatington, Penn The invention provides an emergency appliance adapted to be carried in the tool chest of an automobile and so constructed that in case of breakage of one of the driving axles, the wheel may be removed from the broken part and the emergency appliance connected to the remaining part of the axle and the wheel then connected to the emergency device

HOLDER—A HARNISHFEGER, care of M A Strouse, Main and 2nd Sts, Evansville, Indiana This holder is adapted for use on the side or rear of *an automobile for carrying one* or more extra tires each held on a demountable rim, or for carrying wheels and the like The holder is arranged to take up very little room, to prevent articles from being removed by unauthorized persons and to allow of quickly removing the articles when needed

---

NOTE —Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

---

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade mark work Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor

We also have associates throughout the world who assist in the prosecution of patent and trade mark applications filed in all countries foreign to the United States

If a King's Doctor told you to take Sanatogen—

you would be impressed—for you know that a King's Doctor must be a man of highest professional standing. You would take Sanatogen feeling confident that it would do the things promised; give you fresh vigor, fortify your system as no other tonic could.

Now it is a fact that the private physicians to seven Emperors and Kings, after personal observation of its effects, have endorsed Sanatogen in writing. (See, for instance, the accompanying letters of Dr. Ott and Dr. Kuhn.)

So you see a king's physician might recommend Sanatogen to *you*, if you could consult him—indeed there are over 19,000 practising physicians who would tell you to take Sanatogen, because they all have written us of its wonderfully beneficent effect, of its power to strengthen the nerves, to help digestion, enrich the blood and generally uplift the system in a natural, lasting manner

Such are the credentials of Sanatogen—they should, they must convince you that Sanatogen has a service to perform in *your* case.

Sanatogen is sold by good druggists everywhere in three sizes from $1 00 up.

Dr. Ernest Ott, Late King Edward's physician, Marienbad, writes: "I have been using Sanatogen for a number of years in my practice with excellent results These results have been notably good in the case of elderly people when it was desirable to build up the strength, to stimulate bodily functions, and to improve the circulation of the blood"

Dr. Conrad Kuhn, Physician to the Court of H. I. M., the Emperor of Austria, writes "I have had the very best results from Sanatogen in the treatment of frail, anæmic children and patients suffering from wasting diseases."

Grand Prize International Congress of Medicine, London, 1913

SANATOGEN
ENDORSED BY OVER 19,000 PHYSICIANS

Send for Elbert Hubbard's new book, "Health in the Making." Written in his attractive manner and filled with his shrewd philosophy together with capital advice on Sanatogen, health and contentment. It is free.

The Cleaning Question

Old Dutch Cleanser routs out dirt in a jiffy — quickly removes rust — cuts cleaning cost, time and labor as well as grease and grime. "Settles" the cleaning question.

Fine for cleaning steel, copper, brass, iron and nickel plated metals, floors and floor coverings, lavatories and wash bowls, painted walls and wood work. Contains no caustic or acids.

Buy and try a can or two.

Many uses and Full Directions on Large Sifter-Can—10c.

The World's Largest Locomotive

(Concluded from page [illegible])

tive, has 1,584 square feet of surface.

An interesting fact is that this locomotive has 89 per cent of the total weight of the engine and tender on the drivers, a gain which results from placing a set of driving wheels under the tender. The boiler contains 326 tubes 2¼ inches in diameter and 53 tubes 5½ inches in diameter, and their length is 24 feet. There are 6,418 square feet of heating surface in the tubes, 88 square feet in the arch tubes, and 380 square feet in the firebox and combustion chamber, making a total heating surface of 6,886 square feet. The superheater having a total heating surface of 1,584 square feet, makes the total equivalent heating surface 9,262 square feet. The grate area is 90 square feet.

The tender has a capacity of 10,000 gallons of water and of 10 tons of coal.

The exhaust steam from the right center cylinder passes to the front receiver pipe, and that from the left exhaust chamber to the rear receiver pipe. These pipes have ball and sliding joints which insure flexibility. The front low-pressure cylinders exhaust through the stack through a flexible pipe, and the rear low-pressure exhaust is carried through a feed-water heater, extending the full length of the tender, and is then discharged through a vertical pipe at the rear of the tank.

As showing how, even in mechanical matters, history will sometimes repeat itself, it is interesting to note that as far back as 1863, Archibald Sturrock, locomotive superintendent of the Great Northern Railway, in England, conceived the idea of utilizing the weight of the tender for traction, and built about fifty locomotives which carried an engine and drivers in the tender frame. A photograph and a line drawing by Mr. Herbert T. Walker of this early and most interesting locomotive are shown in the accompanying illustration.

In the Sturrock engines the weight of the tenders loaded was about 57,000 pounds The middle axle was cranked and driven by a pair of inside cylinders, 12 inches in diameter by 17-inch stroke. The wheels were 48 inches diameter and were connected by outside coupling rods.

Steam for the tender engine was drawn from the main engine boiler and was controlled by a separate throttle valve. It was conducted to the tender cylinders through a pipe (visible on the photograph) from the outside of the steam dome. In practice this pipe was found sufficiently flexible without the intervention of compensation joints. The valve gear was the ordinary Stephenson link motion worked by a separate reversing lever on the tender.

The exhaust steam was delivered into a tubular condenser, which was surrounded by the water in the tank, and what remained uncondensed passed away through two short outlet pipes at the rear of the tender. These and other details are clearly shown in the accompanying drawing.

The tractive effort of these tenders was about 5,600 pounds. The engines to which they were attached were the ordinary English freight locomotives of the period; but their heating surface was slightly increased to supply the necessary steam to the tender cylinders. The leading dimensions of the engines were: Cylinders, 16 inches diameter by 24 inches stroke. Driving wheels, 60 inches diameter. Total heating surface, 1,082.26 square feet. Weight in working order, 73,900 pounds.

The tractive effort of the engine was about 11,264 pounds, which, added to that of the tender, made a total drawbar pull of 16,864 pounds.

The hauling power of these steam tender locomotives was nearly double that of the ordinary engines of the same class; for on a level road they drew sixty loaded cars, while the latter could pull only thirty-five cars on the same track.

Although a mechanical success, they were in advance of their time, for the trains they hauled were too long to be handled with convenience, since their length exceeded that of the side tracks. Moreover, on down grades the longer

tenders were difficult to control with the inadequate braking power of fifty years ago. Another reason for their failure was that the tender caught the dust and grit from the engine, making the repair bills heavy.

Finally, the enginemen complained that they had practically two engines to care for instead of one, and their disfavor doubtless contributed to the want of success of these tenders, which, as Zerah Colburn (then the greatest authority on locomotive engineering) said, "deserve to be remembered as a contribution to the practice of auxiliary power."

The Launch of "Shamrock IV"

(Concluded from page 482.)

indeed, that it was necessary to provide extension chain plates in order to get sufficient spread for the shrouds to hold the towering rig in place. A novelty in the rig is the fact that some of the shrouds lead to a point one third of the distance from the masthead; and midway between their point of attachment and the deck is a second pair of spreaders. This method of staying suggests that the mast must be built extremely light in plating.

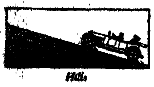
According to Winfield M. Thompson, the yachting expert, who is at Gosport for the purpose of observing the "Shamrock," she will have a sail spread of about ten thousand square feet. If this be true, the sail area will exceed that of "Resolute" by nearly 25 per cent, which is a truly enormous difference. The penalty due to her great sail spread and to the quarter-beam limitation will be large; and it becomes an interesting question whether the great power of "Shamrock IV" will suffice to wipe out the handicap she must give to whichever American boat is chosen, and still have in hand a sufficient margin of speed to make her the winner of three out of five contests off Sandy Hook.

Gustav Hamel

By Major H. Bannerman Phillips

THE finest of Great Britain's fliers lost his life in the attempt to cross the English Channel on May 23d, on his way from Paris to Hendon, where he was to have flown in the "aerial derby" on the afternoon of that day. The race was to start from there about 4 P. M., and after following a more or less triangular course around London, was to finish again at Hendon. Mr. Hamel had gone to Paris in order to fly over to England in the Morane-Saulnier monoplane with 100 horse-power Gnôme engine, with which he intended to compete in the race. He left Villacoublay at 4:30 A. M., landing at Le Crotoy, near Lille, about an hour later. He was afterward reported as having landed at Hardelot, and later at Boulogne. He is said to have left the latter place at half-past 1 o'clock, and afterward to have been seen over Calais. After that all traces of his flight were lost. The weather in the Channel on the 23d was extremely unfavorable for flying. There was a thick mist and a strong westerly wind, and the airman would have known well the significance of this state of things, for he had crossed the Channel in flights about twenty times during his career as an aviator.

The most complete and thorough search was commenced as soon as it was known that there were fears as to his safety. Various cruisers and destroyers and two sea-planes of the British Navy commenced to search the sea for traces of him, and the nature of the weather may be judged from the fact that both sea-planes were wrecked and the rough seas made hard work for the crews of the destroyers as they and the cruisers slowly patroled the Channel and swept the surface of every portion of the sea between England and France, where there seemed to be the slightest chance of finding any clue to the fate of the intrepid airman. The search was continued, both by day and night, as long as there seemed any chance of success, the various vessels keeping touch by wireless all the time. The watch and passengers on the cross-channel steamers also keep a lookout for any pieces of wreckage, and the French and English coasts were



Hills

Heavy Roads

Boulevards

Every-day tests of your lubrication Try them on nearby roads

How soon does incorrect lubrication show up?

Often in one short run.

Consider three types of roads:

Hills. You come to a sharp grade. With one lubricant you must drop to a lower speed. With another lubricant you can climb the hill easily.

Why?

Because the first lubricant is wrong in *body*. Compression and explosion escape past the piston rings. Power is wasted. If the oil is low in *quality*, you must also overcome excessive friction.

Only oil correct in *body* and *quality* will give you full power for the hills.

Heavy Roads. The conditions are very similar to those in hill *climbing*.

Sand, mud or "rough going" bring heavy strains to the motor.

Where an oil correct in *body* and *quality* carries the car along easily, an incorrect oil brings power-waste and excessive friction-drag. Overheating is apt to follow.

Boulevards. Along level roads loss of power is not so often noticed.

But, even on the smoothest roads, only the correct grade of oil will give you full power and full mileage from your gasoline.

To compare the efficiency of any oil with that of Gargoyle Mobiloil, make this test:

Test. Select a steep hill. See how far you can go up on high gear with the former oil. Then clean out your motor with kerosene. Fill your oiling system with the correct grade of Gargoyle Mobiloils. Be sure that operating conditions in both cases are identical. Use the same test. See how much further you go up the hill.

Use the oil specified for your car in our Lubricating Chart, printed in part on the right. A copy of our complete Chart will be sent any motorist on request

On request we will also mail a pamphlet on the Construction, Operation and Lubrication of Automobile engines. It describes in detail the common engine troubles and gives their causes and remedies.

It is safest to buy Gargoyle Mobiloils in original barrels, half-barrels and sealed five and one-gallon cans. See that the red Gargoyle, our mark of manufacture, is on the container.

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are

Gargoyle Mobiloil "A"
Gargoyle Mobiloil "B"
Gargoyle Mobiloil "E"
Gargoyle Mobiloil "Arctic"

They can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants. For information kindly address any inquiry to our nearest office. The city address will be sufficient

Correct Lubrication

Explanation. In the schedule the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used For example "A" means "Gargoyle Mobiloil A" "Arc" means "Gargoyle Mobiloil Arctic" For all electric vehicles use Gargoyle Mobiloil "A" The recommendations cover all models of both pleasure and commercial vehicles unless otherwise noted

examined by searchers of either nation, the French authorities taking an equal interest with the British in the operation, but all in vain.

From what is known of the route taken by Mr. Hamel, it seems probable that, in the first instance, he meant to strike the English coast at Hastings, but found the fog unfavorable to the longer sea-passage and then went farther east, in order to follow the Calais mail-steamer across and thus shorten the sea-journey as much as possible. The steamer having left when he reached Calais, he may have started for Dover, hoping to do the twenty-one miles in as many minutes, but getting caught by the fog, may have lost direction and been carried out of his course and over the North Sea, and finally, when his fuel gave out, he would be forced to come down out of sight of land, when his fate would be sealed. His monoplane was without floats, being intended for overland work, and it could not sustain him long on the surface of the sea, in any case. The circumstances of the voyage bear a painful resemblance to the last journey of the late Mr. Cecil Grace, who was lost in December, 1910, on the return over-sea flight from Calais to Dover in foggy weather.

Mr. Hamel was certainly the most experienced and the most distinguished of Britain's airmen, and he was, deservedly, one of the most popular, partly on account of his achievements, but also on account of his fine manliness and simplicity, to which was added a peculiar charm of manner. He was 25 years of age, and had displayed the greatest aptitude as an aviator of any man of his time; for since he qualified as an airman at Pau in 1911 he had shown himself to be as proficient in cross-country as in exhibition flying, and seemed to have a natural affinity for and knowledge of the air. He was the first pilot to cross the Channel with a lady as passenger, and also the first airman to make the London-to-Paris journey with a passenger in one day, and the first British airman to "loop the loop." He was looking forward with keen ambition to make the first attempt to cross the Atlantic in the Martinsyde monoplane which was being built for the purpose at the cost of Mr. E. Mackay, and which will be described at length in one of the forthcoming issues of the SCIENTIFIC AMERICAN. That his services in the cause of aviation from a national and patriotic point of view were duly appreciated, not only by the British public but by the government, was shown by the following communication in which the Admiralty made known their decision to abandon the search for traces of him on the 26th of May: "It has been decided to suspend the searching operations by flotillas and air-craft which have been in progress for the last forty-eight hours for Mr. Hamel. In relinquishing this quest, the Admiralty desire to place on record their recognition of the services rendered to British aviation by the missing airman. He was without question the foremost exponent in these islands of an art whose military consequence is continually increasing. His qualities of daring, skill, resource, and modesty merited the respect of those who pursue the profession of arms, and his loss, if this must be accepted, is received with deep regret by the officers and men of the Naval Wing of the Royal Flying Corps."

New Meteorological Units in Great Britain.

SINCE the first of May the daily weather reports of the British Meteorological Office have published all barometric pressures in millibars, instead of inches; rainfall in millimeters instead of inches; and wind velocities in meters per second instead of miles per hour. The vertical component of solar radiation, as measured at South Kensington, is given in joules per square centimeter, and its rate in milliwatts. Temperatures, however, are still given in these reports in the old-fashioned Fahrenheit degrees. The Royal Meteorological Society has decided to use millibars in the series of pressure normals for the British Isles, which it is now preparing. The barometers hereafter issued by the Meteorological Office will be graduated in both baromils and inches. (The baromils of the scale-reading are reduced to millibars, or absolute units of pressure, by applying appropriate connections.) Another new unit now used in Great Britain is the leometer (pronounced with the stress on the penult). This is defined as "the potential energy of unit mass raised through 1 meter against an acceleration of one 'leo,' or of unit mass raised through $1/g$ meters against the acceleration of gravity," and is a substitute for Prof. Bjerknes's "dynamic meter." The new unit of acceleration, 1 dekameter per second, is named "leo," in honor of Galileo. The leo and the units derived from it were introduced by Mr. J. W. Whipple, of the Meteorological Office.

An Industrial Education Convention

THE second convention of the National Association of Corporation Schools will be held in Philadelphia from June 9th until June 12th, inclusive. The first convention, held last Fall, took place at Dayton, Ohio; the meetings were held at the National Cash Register building. The meetings of the coming convention will be held in the new auditorium of the Curtis Publishing Company, at Sixth and Walnut Streets.

The National Association of Corporation Schools is an association organised for the furthering and developing of industrial education by employers. Its members are the corporations and firms who have taken positive steps in the forwarding of industrial training by organizing schools in which their new employees are taught what to do and their old employees are trained to higher degrees of efficiency.

Its field of operation lies right alongside the field of operation of the National Society for the Promotion of Industrial Education. The purpose of the National Society is to develop industrial and vocational training in the public schools. The National Association begins where the National Society stops; it takes the public school graduate just entering business and trains him for the particular work of the concern into whose employ he is entering. The purpose of both organizations is to train the man to be of the greatest value to society and business and to enable him to *earn* the largest possible salary.

For the past hundred years the efforts of the great minds of business have been directed to developing and improving the mechanical agencies of production, trade, and commerce. In the agricultural districts, the steam reaper and harvester do the work of hundreds of hands. In factories, every effort has been bent to produce labor-saving machines of greater and greater efficiency. Sixty years ago the "Clermont" ran up the Hudson; now we have the "Vaterland" and the "Aquitania."

It is recognized, in fact, that in our strivings to improve the machines and methods over which our employees are to exercise control, we have taken no steps to improve the employees themselves. Quality of production is not the result of machinery alone, but of brains as well. And we have not taken the trouble to train the brains. From now on it is a man problem.

The realization of the one-sidedness of this development is what has prompted the organization of the National Association of Corporation Schools.

The Curtis Publishing Company, a member of the association, will act in the capacity of host to the visiting delegates at the sessions. Among speakers at the convention will be Arthur Williams of the New York Edison Company, president of the association; E. St. Elmo Lewis, of the Burroughs Adding Machine Company, and Charles P. Steinmetz, of the General Electric Company.

The meetings of the convention will be open to representatives of any business houses who are interested in the possible adaptation of industrial education to their own work and who will be interested in hearing the discussion and in talking with the members.

HARPER'S GASOLINE ENGINE BOOK
By ALPHEUS HYATT VERRILL
This new addition to Harper's "Tell-Me How" series will serve as a simple and practical guide for all those who own, use, or operate gas and gasoline motors. While intended for boys, it will prove of equal value to older readers, as it is more exhaustive than any book on the subject hitherto published—with the exception of strictly technical works. Clear and simple diagrams and illustrations enhance the value of the book. *Illustrated. $1.00 net.*

HARPER'S BOOK for YOUNG GARDENERS
By ALPHEUS HYATT VERRILL
This book has been prepared to show how much profit and pleasure may be obtained from simple gardens, and how to plan, arrange and care for them properly. Mere theories and elaborate methods have been avoided, practicability being the purpose of the volume. School gardening, experimental gardening, ornamental gardening are all explained, and the author shows what can be accomplished at a small outlay in a city back yard or vacant lot. *Fully illustrated. $1.50 net.*

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Possible Addition of Three Battleships This Year

IF the present negotiations and plans of the Navy Department do not miscarry, it is quite possible that provision will be made for the construction this year of three dreadnoughts. The two-battleship programme is certain of adoption, and, also, thanks to the pressing needs of one of the smaller European powers, it seems likely that the Government will authorize the building of a third capital ship of the largest size and power.

The purchase of a large modern battleship by Turkey has made it necessary for the Greek government greatly to strengthen its navy, if it is to hold its present superiority over the navy of its ancient foe. Negotiations have been opened for two of our pre-dreadnought ships, the "Idaho" and the "Mississippi," and the price which is named will be just about sufficient to cover the cost of a ship of the same class as the "Pennsylvania."

Of the more modern of our pre-dreadnought battleships, the "Idaho" and the "Mississippi" are the two which can be best spared; and this, not for the reason that they are not of first-class quality, but because they are what might be called an odd size and do not fit in well with our other ships of approximately the same date. The "Idaho" and "Mississippi," which are sister ships, were built under an authorization by Congress, in which, unfortunately, their displacement was definitely limited to 13,000 tons. They are small editions of the "Louisiana" and "Connecticut," the difference being that they are of 3,000 tons less displacement and of one knot less speed, that their armor is lighter, and that their broadside secondary battery is weaker by the omission of four 7-inch guns.

Except for these differences, they may fairly be considered as of the "Connecticut" class, and, therefore, they are thoroughly representative of the period immediately preceding the advent of the dreadnought. In fact, they were laid down the same year in which the first dreadnought was being constructed. Each ship carries four 12-inch 45-caliber guns and eight 8-inch 45-caliber guns in turrets, and eight 7-inch guns in a broadside battery on the main deck. Each ship has two submerged torpedo tubes of the new 21-inch type. The best recent speed of the ships has been a trifle over 17 knots. They are protected by a 9-inch belt associated with a 3-inch armored deck, and they have from 12 to 8 inches of armor on the turrets. The lower deck and the main deck in the wake of the 8-inch battery are protected by 7 inches of armor.

The purchase of these two battleships would mean a very great increase in the fighting strength of the Greek navy, of which, indeed, they would become the principal and most effective fighting units. At present, the most formidable ship in the Greek navy is the "Giorgios Azeroff," of 9,956 tons, carrying four 9.2-inch and eight 7.5-inch rifles, with twenty four smaller guns. She did very effective work during the Balkan war, and her speed of 24 knots enabled her to attack when she pleased.

It is interesting to note that the powerful dreadnought recently purchased by Turkey is to be met by a Greek battle-cruiser, now under construction at Stettin, Germany, which will carry eight 14-inch and twelve 6-inch guns. But she will not be ready for some time to come, at least a year or two. Hence the advantage to the Greeks of the immediate possession of two such heavily armored ships as the "Idaho" and "Mississippi."

The Promise of Small High-speed Motors

ALTHOUGH *it is still a little early to prognosticate* with strict accuracy the multitudinous detail changes that will make their presence seen and felt in the new crop of automobiles that now are being started on their way through the great factories of the land, straws show which way the wind blows, and there is at least one feature that is practically certain to be very prominent. That feature is the small—or comparatively small—high-speed, high-efficiency four-cylinder motor.

During the past year we have seen the six-cylinder motor, and particularly the small six-cylinder motor, with a bore and stroke of about 3½ by 5 to 5½ inches, climb to great popularity; but now the pendulum seems to be swinging backward, and the small four-cylinder motor bids fair to step out into greater popularity than it ever attained before. Already a number of makers have announced 1915 cars that incorporate motors of this kind, and it is known that several makers, whose past year's activities have been devoted to exploiting small sixes, have practically ready for the market small *four-cylinder cars*, which will be released immediately the demand for sixes gives indication of dropping off.

For one thing, the notable success of a four-cylinder motor in the recent 500-mile race on the Indianapolis Speedway has given both the public and the designers food for thought. This motor, with but 183 cubic inches piston displacement, propelled its car at an average rate of 80.99 miles an hour; the car finished only seven minutes behind the winner, whose motor had 380 cubic inches piston displacement; it handily beat cars with displacements up to 450 cubic inches, which was the limit. But what is far more important, it kept on going—it demonstrated its reliability.

In demonstrating its reliability and its power, this tiny motor brought very forcibly to light the great truth in all engineering matters, that it is efficiency that counts. Efficiency means light weight, reduced friction, and above everything else, lowered operating cost. This is what the average motor-car owner desires. The cost of fuel already is high, in some places it is almost prohibitive. What we must have is high-efficiency automobile motors, and that is what we are going to get.

A few years ago speeds above 1,200 revolutions a minute were regarded as excessive, impracticable almost; yet now there are any number of foreign motors that operate normally at speeds up to 2,000 revolutions a minute. The answer is to be found in bettered workmanship and better materials. Practically all of the attention of foreign designers now is turning toward the production of small, high-speed, high-efficiency motors; they will have none of the big American motors, which are heavy and inefficient, and for that reason expensive to operate.

Only now is this foreign tendency toward high-speed, high-efficiency motors being felt on this side of the Atlantic. Already the practice has made inroads, it is coming slowly, and before long it will come with a rush.

The lightening of reciprocating parts, the reduction of internal friction to the minimum, the perfection of carbureting devices, and a general overhauling of the valve gearing and particularly of the valve timing, all are factors which are contributing to the success of the small high-speed, high-efficiency four-cylinder motor. These engineering problems are being solved slowly by the American designer, but progress undoubtedly is being made.

There will always be a market for the six-cylinder motor-car; there is no doubt of that. But has not the small six-cylinder motor been offered—or rather forced on—the public as an excuse for the lack of perfection of small four-cylinder motors?

To get the power we must have either large cylinders or high speed; we do not require both—not even in racing, as the lesson of that 183-inch motor points. Or, we must have a greater number of cylinders. Smoothness of operation may be left out of the question, temporarily, for the high-speed four-cylinder motor gives for ordinary purposes the continuity of torque that is given by a *six-cylinder motor operating at lower speed*.

So, as the cost of fuel remains high, large cylinders steadily are being relegated to the background, and designers are falling back on greater speed. And this is as it should be, for in lighter engines operating at higher speed we find greater efficiency, and that is what everyone most desires.

That the forthcoming year will see a very marked increase in the popularity of the small high-speed motor of the type under discussion there can be no doubt. It is only to be regretted that someone did not take the cue from our foreign brothers a long time ago.

Physical Law in Economics

AN economic system resembles in certain respects a physical system in a state of strain. Such a system represents a fund of potential energy, since the strains tend to become annulled by readjustment of the matter and energy in the system. Thus, for example, if we seize the center of an elastic band stretched between two supports, and pull it toward one end, a state of strain is created such that upon releasing the hold upon the displaced center, the latter returns to its original position. A point which should be noted is that in such case energy is so redistributed that it passes from regions of *greater* tension to regions of *lesser* tension.

Somewhat similar conditions prevail in an economic system. A number of "owners" possess various commodities to which they attach varying value, varying "tension." They exchange portions of their property until each has such *an assortment of property* as best satisfies his desires. In each case *property* passes from a point where *less* value is attached to it to a point where *greater* value is attached to it. At first sight this may appear to be just the opposite of the conditions observed above, relative to the readjustment of energy. But a closer inspection shows that the analogy holds good. For, as in the case of the elastic we had to consider the passage of *energy* from one half of the elastic to the other, and not the passage of *matter* (which takes place in the opposite direction in this case), so in the present instance we must think, not of the passage of *matter* from one owner to the other, but of the changes in the *energy* of the system. To make this clear consider a simple and somewhat extreme case. Suppose that *A* possesses such a large quantity of some commodity, bread we will say, that he can spare several loaves without feeling any appreciable loss. Let *B*, on the other hand, be nearly starving. In these circumstances it will require but little provocation to induce *A* to part with a loaf and pass it on to *B*. In this case, plainly, *matter* has passed from a point where a low value was attached to it, to a point where it is highly valued. But what are the conditions as regards *energy?*

B was near starvation, and willing to do practically anything within his power to obtain the bread. He was a source of available energy. *A*, on the other hand, was rather indifferent as to his possession of two or three loaves of bread more or less. He was not nearly as ready a source of energy as *B*. After the passage of the bread has been effected, *A*, having now less bread, is somewhat more susceptible to persuasion to do work to obtain bread, while *B* is less so, now that his hunger is satisfied, than he was before. We see, then, that potential energy may, indeed, be said, in this case, to have passed from *B* to *A*, from the point where *greater* value was attached to the commodity to that at which *less* value (tension) was attached to it.

The application of laws of energetics to the field of economics has been foreshadowed occasionally by such writers as Helm, but it cannot be said that the subject is, as yet, at all fully worked out. There seems reason to expect that the future may bring important developments in this direction.

Antivivisection Literature

WE have had occasion in the past to refer to some of the illogical and vicious practices of antivivisectionists. Unfortunately many who read the distorted accounts and misrepresentations emanating from these misguided persons have not the means of distinguishing the truth from falsehood. We have in mind an article which recently appeared in a popular magazine of wide circulation, and which showed pictures of animals seemingly undergoing torture by the applications of various gags and other instruments. *Such pictures are greatly misleading. In the first place*, most of the instruments shown are used only in conjunction with an anesthetic, and secondly, the appearance of ferocity of the gags, for example, is entirely spurious. Such gags are used merely to keep the mouth of the patient open where circumstances demand it, and are in no wise painful, even if no anæsthetic were used. Dr. Keen, in a paper entitled "The Influence of Antivivisection on Character," shows a picture of his little granddaughter photographed with such a gag in her mouth. The child, so far from resenting the process, looked upon the proceeding of being photographed with her mouth wide open as an amusing prank.

It is almost incredible to what lengths of falsehood and suppression of the truth antivivisectionists will go. The impression is persistently conveyed that vivisection is commonly practised without anesthetics. As a matter of fact, even if the operators were as inhuman as antivivisectionists seek to paint them, the use of anesthetics would be imperative in the great majority of cases, because the struggles of a suffering animal would make delicate operations absolutely impossible, to say nothing of the danger of injury to the operator.

It is to be feared that much harm has been done by the grossly misleading publications emanating from antivivisectionist quarters, and we take pleasure in bringing before our readers, in this week's issue of SUPPLEMENT, an exposure from the pen of Dr. Keen, of some of the wickedly deceitful methods employed by these foes of scientific and humanitarian progress.

[illegible]

[illegible] in the [illegible]. It [illegible] to call [illegible]. In order to avoid the tedious delay, an electric [illegible] will probably be installed before the next [illegible] in December. It is estimated that it will cost $20,000 to establish the system.

Electricity and Food.—At the recent session of the National Electric Light Association, in Philadelphia, Mr. T. C. Martin gave an interesting report on the electrical stimulation and plant growth. He announced that vegetables such as radishes and lettuce, when subjected to electrical treatment, had shown a 75 per cent increase in growth over untreated vegetables. Evidently electricity is destined to play an important part in the production of our food.

Electricity from Coal.—According to press reports, Thomas A. Edison is now engaged with the problem of producing electricity directly from coal, and declares that it will be accomplished some day. If Edison succeeds in solving this problem, it will be without doubt his greatest contribution to the good of man. It will mean a great economy in coal consumption if he finds a way of converting all or nearly all the stored energy of coal into electricity. Others have tried to do this but so far have succeeded in converting only a small proportion of the energy.

Wireless in the South Orkneys.—According to the *Geographical Journal*, there is now wireless telegraphic service from the South Orkneys, through the South Shetlands, to the Falkland Islands, and thence to the rest of the world. The South Orkneys, on the verge of the Antarctic, are the site of what has hitherto been the most isolated meteorological station in the world, an important outpost of the Argentine meteorological service. The linking of this station with the world by wireless will be as notable an event as was the recent inauguration of daily wireless weather reports from Spitzbergen, in the Arctic.

Recent Advances in Radio-Telephony.—A great deal of activity is now being displayed in the field of radio-telephony. Many experimenters are reporting progress. In France, Com. Victor Colin and Lieut. Maurice Jeance have transmitted speech over a distance of 150 miles. It will be recalled that these two inventors held long distance wireless conversations five years ago. Mr. William Marconi expects soon to establish wireless telephone communication between his office and his country house, a distance of 67 miles. According to press accounts, Marconi has succeeded in talking with Berlin, which is 600 miles away. This, if true, is startling indeed. However, it will be recalled that, some time ago, press dispatches stated that Marconi had transmitted speech over 1,000 miles. Later it appeared that the communications referred to were in the form of dot and dash signals instead of speech.

Wireless Weather Forecasts for Great Lakes.—A daily weather bulletin for the Great Lakes is now being sent out from the radio station at Radio, Va., according to an agreement just arrived at between the United States Weather Bureau and the United States Naval Radio Service. This bulletin is sent out in two parts. The first consists of code letters and figures describing the weather conditions actually prevailing at 8 P. M. that day at various points along the Great Lakes. The second part of the bulletin is a special forecast of the winds that will probably be encountered on the Lakes. This is distributed to shipmasters on the Great Lakes by the Naval Radio Service during the season of Lake navigation—usually from about April 15th to December 10th—in the same way that weather conditions for the North Atlantic Ocean and the Gulf of Mexico are sent out. The latter service was begun in July of last year. It proved popular, and the Weather Bureau was encouraged to extend the service to the Great Lakes.

Resistanceless Conductors, Hence Permanent Electromagnets?—For many years the laboratory of Prof. Kammerlingh Onnes at Leyden has been the center from which some of the most important advances in low temperature research have been announced. It will be remembered that the Dutch physicist was the first to liquefy helium, the most refractory of all known gases, and that in the course of these experiments the lowest temperature on record, within a degree or so of absolute zero, was obtained. Of late, attention has been centered on the remarkable influence of temperature on the electrical resistance of metals. This resistance is found to become practically zero before the absolute zero of temperature is reached. Recent newspaper accounts state in somewhat vague terms that remarkable new developments have followed in the train of this work on the conduction of electricity at low temperatures. The question arises, what happens to an electric current once started in a conductor of zero resistance? Its energy is not dissipated as heat, since the ohmic effect is non-existent. Does the current continue to flow indefinitely? If so, a closed loop carrying a current would function as a permanent electromagnet. It is rumored that something of this kind has been observed. We shall await further news with interest.

Science

A Mount Rose Snow Sampler and Weigher, designed at the Mount Rose Observatory, has recently been ordered by Dr. A. de Quervain, Director of the Meteorological Service of Switzerland, for the use of the Swiss Gletscher-Kommission in the Alps. The sampler is to be 20 feet long and made in sections of 5 feet to facilitate being carried to the more inaccessible portions of the mountains. During the present season depths of 180 to 260 inches have been reached on several occasions. The density of the snow at these depths has been ordinarily 46 per cent, but the United States Weather Bureau, which has placed one of the samplers in Nevada, reports densities as high as 76.3 per cent.

An Insect Menagerie.—What Prof. Habitte calls his insect menagerie is installed at one of the laboratories of the Jardin des Plantes establishment, and he now has upward of fifty well-arranged boxes or cages where he observes insect life. He thinks that this should be enlarged into an "insectarian," or extensive menagerie, to which the public should be admitted. This is already done in some countries and their usefulness is recognized. No great expense is needed, all that is required being a hall with large tables on which the insect cages are placed in good view, with glass or wire-gauze covers. The insect world is of greater interest than may perhaps be imagined, and no doubt such an enterprise would be much appreciated by the public.

Animals that Never Drink.—It would seem that water is so indispensable to life that no animals could exist without drinking. Nevertheless, Dr. Blanford asserts that the antelopes which live in the sand desert between the salt lake Chilka and the sea never drink. This has been doubted by physiologists, who deny that existence is possible in such conditions, but confirmatory evidence is now adduced by Dr. Drake-Brockman. It appears that since 1910 a troupe of gazelles have lived in the small island Saad-ud-Din on the side of Somaliland, where there is no source of water and where the annual rainfall is less than three inches, so that these gazelles cannot obtain water except after very rare showers. The vegetation is very poor and they cannot supplement the lack of water during the dry season by consuming roots and bulbous plants rich in liquid.

"Lithia Water."—A signal illustration of the importance of the Food and Drugs Act is reported in a recent circular from the office of the Solicitor of the Department of Agriculture. In a case brought by the Government to condemn a consignment of alleged lithia water, offered as a remedy for various serious ailments, it was proved that the water in question contained lithium only in the proportion of about one grain in 10,000 gallons. As the average dose of this remedy as a uric acid solvent is from 5 to 7½ grains three times a day, it would be necessary for a person to drink from 150,000 to 225,000 gallons of the water a day in order to obtain a therapeutic dose. It was also shown that ordinary Potomac River water contains five times as much lithium as this so-called lithia water.

"Tango Foot."—Housemaid's knee, miner's elbow and similar ailments have now a formidable rival in "tango foot." In a recent number of the *Medical Record*, Dr. Gustav F. Boehme, Jr., states that he has recently been consulted by a number of dancers who complained of "pain in the front of the foot." In every instance, he found the same symptom-complex, and on investigation, discovered the cause constant—the modern dance. Says the doctor: "The latter day dances, especially the tango and the maxixe, and to some extent the complicated figures of the hesitation waltz, call for great flexibility of the ankle, with much movement at this point throughout the various intricate steps. The more common movements are those of extension, flexion, and adduction of the foot. The resultant is a constant strain on the extensor muscles of the foot, viz., the tibialis anticus, the extensor longus digitorum, and the extensor proprius hallucis, which in turn produces a tenosynovitis in this muscle group. The commonest tendon involved is that of the tibialis anticus.

The Kara Sea Route to Siberia is nearly always practicable during at least the months of August and September, according to E. Lesshaft, who has published in *Annalen der Hydrographie* a painstaking discussion of the ice conditions in that sea, as reported by vessels during the last forty-odd years. It has happened only once or twice that the sea has been entirely filled with drift ice during the months named; there is normally a large area of open water, but its location varies from year to year. In order that the route may be used, it is necessary for mariners to know in advance only which portion of the sea is open, in order that they may choose the appropriate entrance and steer the most favorable course. The distribution of ice depends upon that of barometric pressure, which can be determined by observations in Nova Zembla and at the mouth of the Obi River, and in both places meteorological stations already exist. As soon as these stations are connected with the world by telegraph, the important problem of using the Kara Sea as a highway to Siberia during a limited period each year will be solved, according to Herr Lesshaft.

Automobile

Cyclecar for Land and Water.—Amphibious cars are not new, of course, but lately one has been brought out in England which appears to be quite successful. It is a sort of combination cyclecar and boat. It is powered with a 4½ horse-power single-cylinder water-cooled motor which drives the vehicle while on land through a chain and two-speed gear set. There is a clutch for changing the drive from the rear wheel to a tail shaft upon which the propeller is mounted. The body, of course, is a boat hull. While the single rear-wheel drive is not ideal for helping the vehicle out of the water and up banks, the possibility of this combination has been demonstrated.

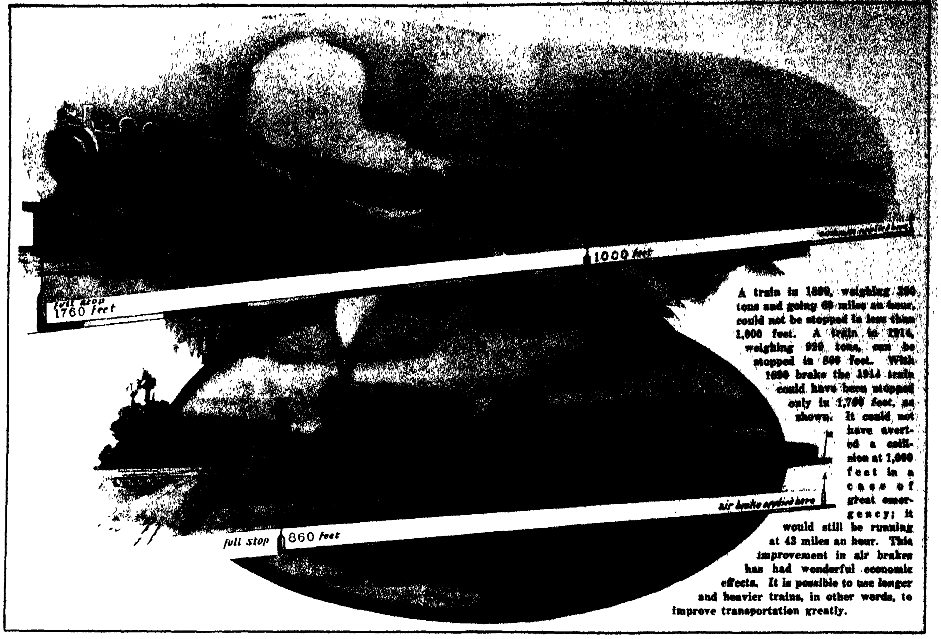
An Improvement in Air Cooling.—A British engineer has been quite successful in increasing the heat radiation of an air-cooled motor by the simple expedient of attaching to the existing iron fins a number of aluminium fins. Aside from increasing the radiating surface, the aluminium is a much more efficient radiating medium than is the iron. The extra fins are merely clamped to the existing iron ones, the only requisite being that a good contact is obtained. In a bench test in which a four-cylinder motor was raced for a considerable time, the radiating fins could at all times be held in the bare hands. Their temperature does not go higher than about 15 degrees above the temperature of the surrounding atmosphere

A Russian Automobile Contest.—The Russian event for automobiles, known as the Czar's Cup, organized by the Imperial Automobile Club, will be held during the month of August. The route is laid out from Moscow, Rostoff, Tiflis, Kherson, to Odessa. Cars admitted to the race must be of standard types published in catalogues at least six months before the date of the event, but any size of motor can be used. Standard four-place car body is to be provided, and the cars are to carry at least two persons, including driver. There will also be held three speed tests on this occasion, one at Rostoff and another at Odessa upon one kilometer length on level grade, and a third at Tiflis on up-grade for several miles length.

A Million Hides for Automobile Upholstery.—As an indication of the tremendous size of the automobile industry, it is interesting to note that in one year approximately 1,000,000 hides are used for upholstery purposes. The ordinary roadster body requires little more than two complete hides, and the touring body about three hides. The average per car therefore is 2½ hides. The average area per hide is about 50 square feet, so that 50,000,000 square feet of leather is used. From the time the hide is stripped from the animal, it requires from 10 weeks to 6 months completely to prepare it for use, the time varying with the quality of the leather. Each hide is split into four grades which are known as hand buffs, machine buffs, deep buffs and splits. The hand buffs are the best and are the part nearest the hair. This is the quality that is most used in the best motor car factories.

Making Bodies with Wood Cement.—Apropos of the suggestion made in this column some time ago that motorcar bodies might with profit be made of *papier maché*, it is interesting to note that a firm of French builders recently has perfected a method of using what is styled wood cement for this purpose, apparently with considerable success. In using the material, the exact composition of which is kept secret, the body is built of a light framework over which is stretched wire netting. The wood cement is then literally plastered on with a trowel. It dries quite hard in twenty-four hours, after which it can be planed like wood and is capable of taking a very high finish. The weight of the finished body is approximately the same as the weight of an ordinary wooden one. One valuable feature of the construction is that repairs are very easily made. In case of breaks caused by collision, etc., it is necessary merely to plaster up the hole and refinish the body. The material does not chip nor disintegrate, is impervious to water, heat or cold, and is practically incombustible.

A Dozen Lamps in Place of Four.—A British accessory manufacturer has attacked the automobile illumination problem in a brand-new manner. Instead of using four lamps, two of them high-power for touring and two much smaller for city driving, he provides no less than twelve small lamps, which are arranged in a row in the filler board between the wind shield and the top of the engine hood. During the time the lamps are not in use they are completely covered by a sliding shutter. For city driving only the two outside lamps are lighted. Where more light is required more lamps are lighted, and when the maximum illumination of the road is necessary, all of them are turned on. The most important feature of the arrangement, however, is that the angle of the group of lamps can be varied at the will of the driver so that any part of the road can be illuminated, sign posts can be shown up, or, on occasion, the reflectors can be shifted so that the light is turned down onto the engine for repairs at night. The lamps are shifted by a simple worm and gearing which is operated by a small hand-wheel placed upon the dash of the car. Another advantage is that the row of lamps does not mar the outward appearance of the car as do the ordinary lamps.



A train in 1890, weighing 280 tons and going 60 miles an hour, could not be stopped in less than 1,000 feet. A train in 1914, weighing 920 tons, can be stopped in 860 feet. With 1890 brake the 1914 train could have been stopped only in 1,760 feet, as shown. It could not have averted a collision at 1,000 feet in a case of great emergency; it would still be running at 43 miles an hour. This improvement in air brakes has had wonderful economic effects. It is possible to use longer and heavier trains, in other words, to improve transportation greatly.

Forty-five Years of Air-brake Evolution

By A. L. Humphrey

Vice-President and General Manager of the Westinghouse Air-Brake Company; Former Superintendent of Motive Power of Chicago & Alton and Other Railroads

FORTY-FIVE years elapsed between the first trial of the air brake and the death of George Westinghouse, an event which has taken, untimely, a discoverer of momentous things and bereft his associates of an inspiring leader. Most people know that the celebrated inventor was throughout that half century so greedy for work that somebody said "he has put a brake on every train but he cannot put a brake on himself"; but the air brake does not figure in the common thought as the basis of any of these later triumphs It is looked upon rather as having sprung from his brain, perfect and complete. To those of us who had the rare fortune in any part of that period to be his colleagues or contemporaries in the manufacture and use of railway appliances this seems a grotesque and romantic notion; for the introduction of the air brake was only its birth. It has had a strenuous infancy, an eventful youth and a recent past of wonderful development. Maturity it cannot reach until transportation by rail ceases to progress The quick action triple valve, brought out by Westinghouse in 1887, and the high-speed feature of the passenger train brake, added in 1894, have rendered a continuous service which in length of time, universality of application and degree of excellence is unapproached by any other mechanical device in common use at the present time upon railways The past ten years have seen further notable advances.

A train in 1890, weighing 280 tons and going sixty miles an hour, had an energy of 33,000 foot-tons. The best air brake of that day, working to the top of its strength, could not stop that train in less than 1,000 feet. A train in 1914, weighing 920 tons and going sixty miles an hour, had an energy of 111,000 foot-tons, almost four times as much as what had to be dissipated in stopping the train of 1890 With the 1890 brake the 1914 train could have been stopped in perhaps 1,760 feet. As it passed the 1,000-foot mark it would still have a collision energy of 48,000 foot-tons (one and one-half times what the 1890 train had before the brake was applied), and it would still have 760 feet to run. That 1914 train with a 1914 brake can be stopped in 860 feet. At that point the same train with an 1890 brake would still be running forty-three miles an hour, with a collision energy of 57,000 foot-tons, or about twice that contained in the 1890 train at the beginning of the stop. It is not so much that the 1914 brake is bigger, as that it is different, and the laboratory has toiled through forty-five years to produce this doubling of the air brake's efficiency.

Safety Is Not the Sole Benefit of the Air Brake.

Another impression which many people have is that safety is the sole benefit from the air brake. That phase is a commonplace When you read that an engineer did not stop you know that he probably could have stopped, since he had the means. To those who make or use it—to the railway manager racking his brain for ways to curtail controllable expense in order to meet other expense which is beyond control, the air brake has been and is one of the most effective of economizers. Think what it does The train running at speed can be quickly stopped. What follows? That you dare run it at speed! And how does speed effect economy? By increasing the revenue which can be earned in a day by the crew; by the locomotive, which can haul a longer and heavier train; by the car, which will hold more tons; by the trackage, which can accommodate more trains a day; by the traffic solicitor, who can bring more freight and passengers if service is quicker. It is not alone that longer and heavier trains and more of them can be operated at speed, because the air brake will stop them when there is danger. Countless station stops, slow-downs and applications while descending grades are made to one emergency stop. The time saved in such routine operations and the larger use of plant, especially at junctions and terminals, due to quick stopping, without damage to cars or cargo, is one of the most important results accomplished in the whole brilliant history of organized railway endeavor for economical and efficient operation.

The commonest measure of economical railway operation is the average train-mile load. For the United States this average has risen from 175 tons in 1890 to 409 tons in 1912. Is it surprising that the railways have given and are more and more giving the most eager and systematic co-operation to the manufacturer in the development of air-brake improvements?

The growth of the brake to carry the modern burden has steadily progressed. Higher speeds, heavier vehicles, longer and heavier trains and their greater frequency increased the amount of work required of the stopping device. The effort consumed in stopping a given train going twenty miles an hour is four times that required at ten miles per hour. The brake shoe, which performs its function through friction against the wheel, is at a disadvantage, which is aggravated as the amount of work required within a given distance increases. A further loss occurs as the greater force is exerted through the foundation brake rigging and because of the longer time taken to obtain full braking power with large cylinders and larger trains. With longer trains, also, and their greater frequency, and with an increasing number of parallel tracks (each liable to accidents which pile up obstacles on adjoining tracks), an increase in the volume of air used interferes with the prompt and uniform response of the brakes to the manipulation of the valve, both when applying and releasing. This makes recharging more difficult and demands a larger available supply of compressed air. Another tendency which was manifested with enlarging train units was that the time elapsing between the action of the brakes at the head end and at the rear end of the train caused a bunching or stretching out of the slack between cars, and this interfered with its smooth handling. The increased risk, moreover, introduced with a greater number of parallel tracks and greater frequency of trains made mandatory that full energy of braking power be available at any time.

To enable the brake mechanism to perform this augmented and more complex task, the most obvious and essential step was to insure the best of use of the device as it stood. A poor brake well maintained and operated in the best possible manner will give better service than the best brake if neglected or carelessly handled. This meant systematic instruction of those responsible for handling of trains in service and for the care, inspection and maintenance of the brake mechanism. Both railroads and manufacturers developed trained corps of experts and special methods and apparatus for testing and repairing and provided technical literature and instruction paraphernalia, including elaborately equipped instruction cars and rooms. By organized efforts along these lines increasingly

The Langley "aerodrome" with the pontoons provided by Mr. Curtiss.

The Langley Aeroplane Construction and Control Mechanism

By Our Staff Correspondent at Hammondsport

THE brief flight of the Langley aeroplane recorded in these columns has since been several times repeated, and always with the same steadiness on the water and in the air. Efforts are now to be made to increase the thrust to meet the greatly augmented weight and resistance due to the added floats and trussing which unites them with the aeroplane proper. The present weight with Mr. Curtiss as pilot is 1,170 pounds; the old weight with Manly as pilot was 830 pounds. The increase of weight is, therefore, 40 per cent; the increase of flying resistance is of a like order, possibly greater, due to the augmented drift on the wings, and the head resistance of the floats and framing. It is believed that careful adjustment and some further trials will enable the engine to bear this excessive load in longer flight. If the launching had been made from ice, with light skates as the only added weight, a prolonged flight could have been made on the first trial, since there would have been an excess lift of approximately 300 pounds, and, of course, much less head resistance. Or if a slightly stronger engine were substituted, no careful adjustment would be required to achieve long flights.

The Langley aeroplane may be viewed either as a type or as an individual machine. As a type it seems to have been invented by D. S. Brown, and exhibited as a kite, in 1873, before the Aeronautical Society of Great Britain. The tandem arrangement of supporting surfaces also appeared in Hargrave's kites, and in Kress' aeroplane of 1893 and earlier; also in Langley's steam model flier of 1896; Montgomery's great glider of 1905, Blériot's first successful flier, patterned after Langley's large machine, also in some present-day fliers, notably Colliex's huge tandem biplane flying-boat, which is reported to have a useful load of 4,000 pounds, or a range of 1,000 miles, and has recently lifted with ease from the Seine Langley's successful steam models and gasoline models were of both monoplane and biplane types.

Floating the machine.

The Langley tandem aeroplanes are unique and highly original throughout. The large machine now at Hammondsport, which antedates its quarter-scale model, flown successfully above the Potomac in August, 1903, is a marvel of design and workmanship. It is the first aeroplane in history provided with an internal combustion motor; the first capable of carrying a man in sustained flight, the first man-flier with good enough inherent stability to take care of itself in moderate weather.

Langley's large "aerodrome"[1] is a tandem monoplane driven by twin propellers just aft the front planes. As seen from a distance, it shows four great dragon-fly wings and a long, double tail, all mounted on a long open steel frame, with a steering rudder beneath and abaft the center. The propellers on either side are connected by bevel gears to the engine ensconced in the frame just aft the fore wings. Posts for the numerous stay wires just above

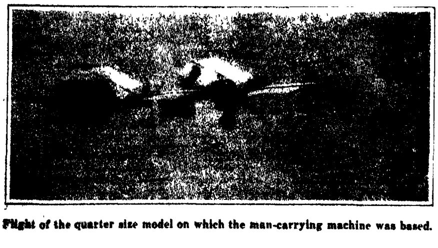
Ready for flight.



Flight of the quarter size model on which the man-carrying machine was based.

---

[1] The term "aerodrome" was used by Langley to connote an "air runner" or any kind of heavier-than air flying machine. It is now generally applied to an assemblage of buildings and grounds used for flying

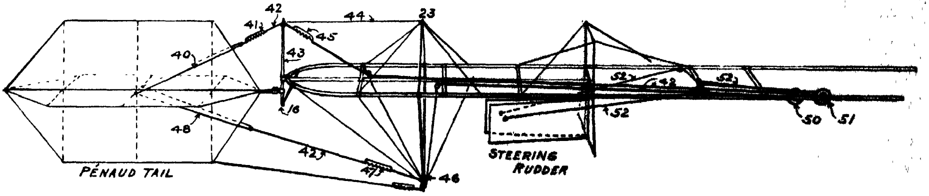
and below the frame at the wing spars, and a bowsprit protrudes from the prow. No running gear was provided, as the flier was originally to be shot from a catapult above a houseboat, and to land in the water after its voyage. The recently added pontoons, two flat ones in front and a cylindrical one at the rear, show conspicuously in the general view, especially when well out of the water.

The whole machine weighed originally 830 pounds, including the pilot; spread 1,040 square feet of wing surface, measured 52 feet from tip to tip, and 52 feet from the point of its bowsprit to the end of its tail; soared at 33 feet a second, and at a 10-degree angle of flight. The wings measured each 11 by 44 feet, arched one in eighteen at one fourth the distance from their front edge, and were covered only on their upper side. The double rudder, at the extreme rear, measured 95 square feet each in its horizontal and in its vertical surface. The vertical steering rudder measured about one square yard, and opened at the rear like a weather vane to give more grip at small angles.

The propulsion plant was most carefully designed and constructed. The gasoline engine weighed, without accessories, 125 pounds, and developed 52.4 horse-power in actual test at 930 revolutions a minute. With all accessories, including radiator, cooling water, pumps, tanks, carbureter, spark-coil, and battery, it weighed 200 pounds, or just 3.81 pounds per horse-power, a fine showing for the opening of the twentieth century. It could run ten hours continuously under full load, consuming about one pound of gasoline per horse-power per hour. Its five cylinders, arranged radially round a single crank-shaft, were made of steel lined with cast iron, and measured 5 inches in diameter by 5½ inches in stroke. By means of bevel gears it drove the twin screws, supported on steel tube brackets on either side of the steel tube frame, at 700 revolutions per minute, giving a thrust of 480 pounds, the screws being very nearly true helices, 8 feet in diameter, of unit pitch ratio, and 30 degrees width of blade, carefully formed of three radial arms covered with canvas.

Good inherent stability and fair manual control characterized the original machine. The lines of lift, propeller thrust and forward resistance passed through its center of mass, thus providing for projectile and gravitational equilibrium. The wings were set at a fair dihedral angle to give lateral stability. The rear rudder in level flight met the air at a negative angle of incidence, so as to check any serious diving; it was elastically connected to the main frame struts to dampen pitching, it was hinged to move up and down, but prevented by stays from moving sidewise. The pilot, seated in a little canoe under the fore wings, could steer up and down by working the big tail with a hand wheel, and steer right and left by working the wind vane rudder with another hand wheel. He had no lateral rudder, ailerons, or warping wing tips to control the lateral poise; but he could shift his weight several feet to right and left and fore and aft. Altogether the machine was quite as manageable as the famous Antoinette monoplane and Voisin biplane, which, in 1909 and subsequently, voyaged scores of miles in stiff winds, and achieved world records and prizes at international meets.

From what precedes it may be judged that the large Langley aerodrome of 1903 was capable, and is still capable, of sustained free flight with a man. It was intended only as an experimental aeroplane, to prove the feasibility of human flight, then to be provided with landing gear and otherwise better adapted to practical uses. But for the accidents in launching this machine, in September and December, 1903, Langley would undoubtedly have inaugurated the era of successful human flight, if the present day flying can be called successful in a broad sense. As it is, he has had no superior in the development of aviation; for he made contributions to the fundamental science of aerodynamics; made numerous models propelled, first by rudder, then by steam, then by gasoline; and finally produced a full scale machine that can carry a man as it was designed to do. When finally the aeroplane shall become an important agency in the civil and serious business of the world, who will be called its inventor? Langley's work will, doubtless, rank level with the best that has yet been done in the world of aviation.



Stabilizing and steering mechanism of the Langley aerodrome.

To maintain equilibrium Langley relied mainly on the use of the Pénaud tail. The combined Pénaud tail and rudder controls the longitudinal equilibrium by movement in the vertical plane under the combined influence of its initial negative angle and the elasticity of its connection with the frame, the flight being kept as nearly as possible in a straight line, by the vertical surfaces of the tail. The tail swings up and down by reason of its pin connection with the vertical tube 16. The bridle 40, connected with the center of the tail on its upper side, passes upward, where it is connected with the spring 41, which in turn is connected with a single wire rope 42, passing over a pulley mounted on the top of the post 43, guyed to the upper side post by the wire 44. After passing over the pulley the wire rope 42 is connected with the spring 45, around the two ends of which it forms a loop, and from there it passes down to the plane of the main frame, and through suitable blocks to the aviator's control wheel 50, convenient to the right hand. The wire from this point passes through various pulley blocks toward the rear of the machine and through the pulley block 46 mounted on the side near the bottom of the rear lower guide post. At a short distance beyond this pulley it is connected with a weaker spring 47, the other end of which is connected by a second bridle 48, with the under side of the Pénaud tail. The control wheel can be automatically locked in any position in which it may be when the aviator removes his hand from it. For rising or descending the aviator can swing the Pénaud tail from its extreme upper position to its extreme lower position by a small motion of his hand. The control of the steering rudder is effected by a steering wheel 51, a continuous cord 52, passing from the steering wheel through suitable pulleys to either side of the steering rudder.

X-Ray Analysis of Crystals

By John W. N. Sullivan.

TWENTY-FIVE years ago Lord Rayleigh discovered that the brilliant coloration of crystals of chlorate of potash when white light falls on them is due to selective reflection. From all the rays of different wave-lengths which constitute white light the crystals select rays of certain wave-lengths, within very narrow limits, for reflection. This effect is due, as Lord Rayleigh showed, to the existence of regularly spaced twinning planes in the crystal parallel to the reflecting surface, and he illustrated the effect by reflecting a high-pitched note by a series of parallel muslin sheets stretched tight and evenly spaced.

At the present time, using X-rays instead of white light, investigations are being made on the actual arrangement of the atoms in various crystals, by observing the manner in which they reflect X-rays from their various faces.

A pencil of X-rays of uniform quality is reflected from a face of a crystal when, and only when, it meets that face at the proper angle of incidence. There is a certain relation connecting the wave-length of the X-radiation, the proper angle of incidence, and the spacing of the planes in which the atoms of the crystal are arranged, which planes are regularly spaced and parallel to the face of the crystal.

It is evident that by observing the correct angles of incidence for reflection at the various crystalline faces for the same pencil of X-rays, and deducing therefrom the different spacings of the atomic planes parallel to each face, we can, by analyzing these results, deduce the actual distribution of the atoms throughout the crystal, and even build models illustrating the atomic constitution.

For these experiments we require a homogeneous pencil of X-rays, and bulbs having rhodium or palladium antikathodes are very suitable, as they last well, their line spectra are very intense, and the wave-lengths are of convenient magnitude. The exactness of the reflection effect is such that the two constituents of the principal rhodium line, which is really double, are just separated by reflection at the cleavage face of the diamond.

A crystal is considered to be made up of groups of atoms. Each group is supposed to contain as few atoms as possible consistent with the requirement that the whole crystal may be built up by packing all these groups together, the groups in any one crystal being similar and similarly oriented.

If now we choose any point in a group as characteristic of that group, then by choosing corresponding points in every other group in the crystal we get an assemblage of points which indicates the relative position of any one group with respect to any other group in the crystal. The assemblage of points obtained in this way is known as a [illegible] mental importance in [illegible] a crystal.

The large class of crystals [illegible] are the simplest in construction [illegible] reference to their space lattices, [illegible] divisions.

In the first division, which is called the [illegible] representative points for each group are placed at the corners of a cube, the whole lattice consisting of a repetition of this arrangement in all directions in space. In the second division, the centered cubic division, there are representative points at the corners of a cube and at the center of the cube. The third division, known as the face centered cubic, is characterized by having its representative points at the corners of a cube and at the middle points of the faces. By building a model we see at once that the relative spacings of the planes in these three divisions are different, and this causes corresponding differences in the angles of reflection of some standard line, when using the X-ray method of analysis; so that these three types of lattice may be at once distinguished from one another.

We now come to a case of great importance. Sodium chloride and potassium chloride have long been known to be of similar construction, although until quite recently the precise nature of the construction has not been known. By using the X-ray method of analysis, however, we find that the sodium chloride crystal has the characteristics of the third class of lattice, and the potassium chloride crystal of the first type of lattice. In addition, it appears that the elementary group, or pattern, contains the same number of atoms in each case. Prof. Bragg explains these facts as follows: "Suppose that we place chlorine atoms at the corners of a cube and at the centers of the faces and sodium atoms at the middle points of the edges of the cube and at the cube center, and take this to represent the structure of sodium chloride. Potassium chloride may be derived from sodium chloride by replacing the chlorine atoms of the structure by potassium. Now, it appears from a number of mutually supporting indications that the contribution of an atom to the reflection effect depends on its atomic weight only. The atoms of potassium and chlorine are of very nearly the same weight, and can be looked on as equivalent. If this is done, the structure of potassium chloride is, in effect, the simple cubic. But there is a great difference between the weight of sodium and chlorine, and the face-centered arrangement of the chlorine atoms taken separately gives its character to the whole sodium chloride structure. All this agrees with experiment. But there is more. The presence of the sodium atoms among the chlorine, arranged, as a matter of fact, on a face-centered lattice of their own, modify the purely face-centered character of the spectra, and experiment shows that the modification is exactly such as theory predicts."

The simple crystals have been analyzed and the structure of many of the more important cubic crystals is known. The complex structure of the calcite series has been determined, and something has been discovered of the still more difficult structures of sulphur and quartz. In each of these cases we require to determine not only the lattice, but the arrangement of the atoms in the group which is represented by each point on the lattice.

Among cubic crystals, one of the most interesting is the diamond. The carbon atoms are arranged in a most beautifully symmetrical pattern, each being at the center of a regular tetrahedron composed of its four nearest neighbors. Rings of six carbon atoms form a predominating feature. Planes perpendicular to a cube diagonal are arranged in a curious way, the spacings and spacings, large and small, in the direction of [illegible].

[illegible] has exactly the same structure as the diamond, [illegible] planes of the [illegible] last mentioned [illegible], zinc blende [illegible] and sulphur [illegible].

Iron pyrites has a rather more complicated structure, which explains at once the curious disposition of the striations on its faces, while sulphur has eight interpenetrating lattices, quartz three of silicon and six of oxygen. In the last two cases the lattices are regularly spaced along the long axis, but not in other directions.

The atoms of a crystal are, of course, in movement to an extent which depends upon the thermal state of the crystal, the motion increasing as the temperature rises. According to theory, this must tend to destroy the intensity of the spectra, particularly those of a higher order, a deduction which is confirmed by experiment. The angles of reflection diminish and the spacings of the planes increase as the crystal expands by heat, which suggests a method for measuring the coefficients of expansion of crystals.

But, besides the light thrown upon the structure of crystals by the X-ray method of analysis, valuable information is afforded us respecting the X-rays themselves.

In the *Proceedings* of the Royal Society for last year Prof. Bragg has shown that by the reflected X-rays a method may be derived for the spectroscopic study of the X-rays.

Using an ionization method, he has measured the intensity of the rays reflected at certain angles by the crystalline faces, and showed that the distribution of these intensities gave evidence of a series of maxima and minima, which gives a first approximation to the distribution of energy in the spectrum considered as a function of the wave-length.

A Close Shave in the Air

WITH only a few flying machines in the world and the whole ocean of air to fly in, one would think a collision of aeroplanes to be next to impossible. And yet more than one of such accidents have occurred, and the results were, of course, disastrous. Certainly there would seem to be less excuse for an encounter in the three-dimensional space of the aeroplane's domain than in the two-dimensional planes of travel that land and sea vehicles must adhere to. The aerial pilot may leap over or dive under his adversary; and yet with no fixed lanes of travel it is evident that much confusion is liable to arise, particularly as flying machines are very fast and there is no system of signaling between them.

At the recent aviation meet at Heliopolis, a collision between two aeroplanes was so very narrowly averted as to send thrills of horror through the spectators. In this case the proximity of the aeroplanes was due to the fact that they were rounding a pylon and were trying to hug the course as closely as possible. There were three aviators in the air, Guillaux, Chevillard, and Olivier. Suddenly Guillaux was seen to approach Chevillard, and it looked as though he would surely strike the right wing of Chevillard's biplane as it was banking for the turn. By the barest margin the monoplane cleared the biplane, and the two aviators continued their flight, undaunted by their harrowing experience.

By rare good fortune one of the correspondents of *L'Illustration* happened to catch the two aeroplanes with his camera at the very moment when the collision seemed imminent. We have used this remarkable photograph, by courtesy of *L'Illustration*, for our cover illustration. It shows by what a small margin a serious accident was averted. It is the first photograph ever taken of an aerial encounter. In the distance may be seen the biplane of Olivier.

Scientific and Animated Gyrostats

AT the recent Conversazione of the Royal Society, Dr. J. G. Gray exhibited gyrostats with accessories and a series of what may be called "animated" gyrostats. These latter consist of gyrostatic acrobats, bicycle riders, and gyrostatic motor cars, both two-wheeled and four-wheeled. The models exhibit Dr. Gray's methods of endowing gyrostatic devices, mounted on moving bodies, with complete stability. The devices, so mounted, are available for directing and forcibly maneuvering the bodies. One of the two-wheeled cars is provided with a gyrostatic "chauffeur," which stabilizes the car and presides at the steering wheel. This car illustrates the action of directing and stabilizing apparatus for use on torpedoes, airships, and aeroplanes. A further form of two-wheeled car demonstrates methods of stabilizing and maneuvering an airship by means of forces derived from the gyrostats, which apply [illegible] to the moving body. Dr. Gray's [illegible] and motor cars can be steered by the wireless transmission of electrical waves.

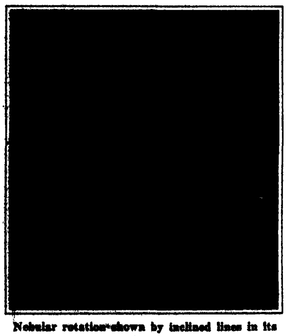
The Discovery of Nebular Rotation

By V. M. Slipher, Lowell Observatory

BEYOND the solar system the astronomer is concerned with two kinds of objects, stars and nebulæ. That these are related by some general process of evolution has long been thought. Laplace's celebrated nebular hypothesis is an attempt to outline how an extended nebula might evolve through contraction under the force of gravitation into a star like our sun and be surrounded by planets in consequence of the nebula's rotating during the process. This was, as he pointed out, speculative, but Sir William Herschel's epoch-making observations of nebulæ in various degrees of condensation led him to a like theory. Herschel found gradations in nebulæ from the most diffuse to those scarcely distinguishable from real stars.

During the last thirty years the spectroscope and the photographic plate have added vastly to our knowledge of both stars and nebulæ. And there have come to light so many hints of an evolutional process running through and connecting these bodies, that we are to-day using many descriptive terms which tentatively assume an orderly evolution. Finding this law is the problem that faces the astronomer to-day, and now, as in the days of Swedenborg, the geologist wants the answer, that he may the better know the earth's past and future.

In the investigation of the spectra of the celestial bodies we to-day use the spectrograph, a photographic spectroscope, which receives the light through a very narrow window or slit, adjusted into the focus of the telescope. After entering the slit the light passes through a lens to prepare it for the prism, which next receives it and passes it on, refracted and dispersed, into its component colors, to the camera. Here the light falls on a photographic plate. In the telescope, stars are always bright points of light, planets bright disks, nebulæ faint patches of various shapes and sizes. Thus if the telescope be directed on a star the spectrum will be a very thin band; if on Jupiter, a broad band, running through the colors from red to violet, but interrupted by the numerous spectral lines. It is these spectral lines—always different for different substances—that tell us of the presence of the chemical elements in the stars and nebulæ, and also of their motions; for, if approaching us, the lines are all shifted toward the violet end of the spectrum; if receding, toward the red, the amount of the shift telling how rapidly. A terrestrial spectrum is always photographed beside the celestial spectrum, to enable us to make all desirable comparisons and measures. On such a spectrum photograph of Jupiter, made with the slit on his polar diameter, the Jovian lines will cross the spectrum band at right angles, as do the comparison lines; but if the slit be placed on the equator of Jupiter, then his lines will be inclined in consequence of his diurnal rotation, which causes one edge of his disk to approach us and the other to recede. By measuring the inclination of the lines, the length of the planet's day can be deduced.



Nebular rotation shown by inclined lines in its spectrogram.

It was the application of this method, made at Flagstaff a few years ago, which showed the length of the day of Uranus, previously unknown, to be about ten and one half hours.

These methods, known for twenty years, have only recently been applied to the nebulæ. The reason for this delay in so studying the nebulæ with the spectrograph is doubtless due to the faintness of their spectra. The slit can receive light from only a thin line of the already faint nebular image, and the prism disperses it into a spectrum that is so faint as to require not only hours, but nights and even weeks, of exposure before the most rapid photographic plate will give a useful negative.

Spectrum photographs of an interesting nebula in the constellation of Virgo, catalogued as N. G. C. 4594, made with an especially efficient spectrograph attached to the 24-inch refracting telescope, show the nebular lines unmistakably inclined, and therefore prove the nebula to be rotating about an axis. This nebula may be seen in the accompanying illustration from a direct photograph made with the 40-inch reflecting telescope of this observatory by Mr. C. O. Lampland. The elongation of the nebula is east and west. The slit of the spectograph was placed over this long axis, which would show the axis of rotation to be nearly north and south. It doubtless rotates about the central condensation, from which it seems to extend into a more or less disk-like mass which appears spindle shaped, because we must look against its edge. If Laplace could have seen this nebula as it really is, he might have found in it a satisfactory illustration of his nebular hypothesis.

While it has long been thought that the nebulæ rotate, this actual observation of the rotation was almost as unexpected as the discovery that this and other similar nebulæ have enormously higher velocities than do the stars. The discovery of the rotation of this nebula has opened a new field for investigation, which can hardly fail to throw some light on the important subject of stellar and nebular evolution.

The American Radio Relay League

THE American Radio Relay League has been organized in Hartford from the Radio Club of Hartford, a group of wireless enthusiasts and experimenters. This league is intended to organize and link together the best amateur wireless stations in the United States and Canada. According to our information, there are some 300,000 of the amateur wireless telegraph stations in existence and actually receiving and transmitting messages at the present time. It only remains to link the best of these together in order to make it possible for an amateur in Maine to communicate with an amateur in California.

Already the league is transmitting from Hartford, Conn., to Buffalo, N. Y., through Northampton, Mass., and Westfield, N. J. Certain hours in the evening are prearranged, and these messages are relayed through by courtesy. With conditions favorable, a message is sent through to Buffalo, delivered, and the answer received back within the hour.

Up to the advent of wireless telegraphy, and its popular use by the lay public, the only way to transmit intelligence was by the assistance of the telegraph or telephone companies, or else the postal facilities of the Federal Government. The popular adoption of wireless telegraphy makes it possible for the private citizen to bridge distances without the aid of either the big corporations or the Government.

Amateur wireless operators are requested to communicate with the Radio Club of Hartford and secure blank forms, which, when filled out, are used for appointing the official relay stations.

The Wanamaker Transatlantic Machine

IT is announced that the Rodman Wanamaker transatlantic machine which Glenn H. Curtiss is building at Hammondsport will soon be ready for its first trials. It is stated that the machine is almost ready to be assembled. The motors were recently subjected to a 30 hour continuous run. There are two of them, each of 100 horse-power. Originally it was intended to use a single motor of 200 horse-power, but Lieut. Porte advised that two well-tried stock motors should be used instead of a single large experimental power plant. It is said that the Wanamaker machine is not as large as originally intended. Its length is only thirty feet.

The Current Supplement

IN this week's issue, No. 2007, of our SUPPLEMENT, Dr. F. H. Hatch gives a review of current theories of ore genesis.—The reduction gear and dynamometer of the United States steamship "Neptune" is described in detail.—S. Chapman writes on the number of stars and the light received from them. An important paper which should be read by all is Dr. W. W. Keen's "The Influence of Antivivisection on Character." A rapid system of water filtration on a large scale is described and illustrated.—J. Boyer contributes an article on pneumatic grain elevators.

Wright Flying Licenses

IT is announced that the owners of aeroplanes which infringe the Wright patents must pay a fee of $1,000 to the Wright Company and, in addition, $25 for each day or part of a day that the machine is operated or exhibited for profit or prize. The license expires on December 31st. Aviation meetings are by no means as popular as they were five years ago. It is not likely that professional aviators will therefore eagerly accept the Wright conditions.

Mistletoe thrives on the Western coasts to an extent not approached in the East. In many places this parasitic growth is responsible, directly or indirectly, for a considerable loss of timber.

The Super-dreadnought "Queen Elizabeth"

The First Battleship to Mount 15-inch Guns

By Oscar Parkes

THE battleship "Queen Elizabeth," and her sister ships, "Warspite," "Valiant," "Barham," and "Malaya," mark the commencement of a new era in British naval construction, being the first ships to carry the new 15-inch gun—a weapon which discharges a projectile of 1,950 pounds weight against the 1,400 pounds of the 14-inch and latest 13.5-inch guns In addition, they will be the first ships other than scouts and torpedo craft to be driven solely by oil-fuel, and with their speed of 25 knots—which is likely to be greatly exceeded on trial—will have the distinction of being the fastest battleships afloat

Although officially designated 'battleships," the "Queen Elizabeth" class are becoming looked upon as "battle-cruisers" from the fact that their speed is four knots in excess of the standard speed for line ships and obviously intended for overhauling the enemy's rear-guard and forcing an action—the generally accepted rôle of the battle-cruiser. In later ships a return has been made to the usual speed of 21 knots, the "Royal Sovereign" class which are now under construction having the same armament as the "Queen Elizabeth," but on something like 2,000 tons less displacement · the decrease being accounted for by the drop in speed, and the saving in machinery weight, engine room, and therefore dimensions

The adoption of the 15-inch gun is, of course, typical of the British policy, which is "superiority both in numbers and individual power." It would have been simpler to have met foreign ships armed with ten or more 14-inch guns by the construction of similar ships, but equality does not postulate annihilation, and this is what will probably be the fate of the "Queen Elizabeth's" opponents British gunnery experts do not, however, favor the placing of more than ten big guns in a ship, and even had the Admiralty been anxious to retain the very successful 13.5-inch gun which has appeared in the "Orion," "King George," and "Iron Duke" types, their reply to say the "Pennsylvania" would have been a ship with ten of these pieces—twelve or fourteen such guns would have been more than can be adequately controlled, according to British practice. Eight guns being the ideal group, it becomes obvious that the only way out of the difficulty of providing a better and more powerfully armed ship lay in increasing the caliber of the guns—hence the advent of the 15-inch and the probable early reappearance of the 16.25-inch gun when the smaller weapon becomes generally adopted elsewhere.

In appearance the new ships will be very much like the "Iron Duke" class, with the amidships turret suppressed and an extra mast aft, instead of the stump between the funnels, which is such an unsightly feature of these vessels. There is the usual pile of chart houses and bridges forward, the heavy tripod mast with a double-storied control-top, big funnels, and torpedo net defense. The big guns are in four 14-inch turrets along the center line, the third and fourth superfiring axially. In casemates in the superstructures and along the upper deck are spaced the sixteen 6-inch rapid-fire guns, while eight 3-inch anti-aero guns are distributed over the upper works, and four more are carried at the stern of the ship. There are five torpedo tubes (21-inch), two on each side and one in the stern, all below water.

The dimensions of the "Queen Elizabeth" are: Length, 650 feet over all; beam, 94 feet, and draught, 27½ feet, giving a displacement of 27,500 tons.

For water-line protection there is a 13½-inch belt extending from the base of the foremost turret to just short of the aftermost, with 6-inch continuations to within about 20 feet of the extremities. Above is a 10-inch strake along the lower deck side amidships with 8-inch over the battery, the gun positions in the superstructures being similarly protected. Amidships the hull is covered with thin armor—two or three inches, probably—down to the keel, and a most elaborate system of internal under-water protection reinforces this. The thickness of the armor decks and bulkheads is uncertain.

The great speed has only been attained by the substitution of oil fuel for coal, and a supply of 4,000 tons of this can be stored. With Parsons turbines generating 58,000 nominal horse-power and driving four screws, the designed speed is 25 knots.

Of the five ships, only the name ship and the "Warspite" have as yet been launched (March), and these two are due for completion in October; the remaining three should join the flag between Spring and Summer, 1915. At present afloat the only ships which can compare with them in fighting power are the "Texas" and "Oklahoma" classes, with the Japanese "Kongo," the Chilian "Al Latorre," and the Turkish "Rechadieh."

Psychophysical Tests for Falsehood

By Dr. Anton Rose

FALSEHOOD, when practised by an expert, is not easily detected by the most careful scrutiny of the liar's appearance and manner, but extraordinary and successful means for its detection have been developed from the study of experimental psychology. The principal psychophysical factors employed in this method are the character and rapidity of the mental process known as association of ideas. The word "horse," for example, may suggest anything related to horses—a stable, a familiar breed, a characteristic color, such as bay or chestnut, a race track, etc.

In criminal jurisprudence this fact is utilised by uttering a word and requiring the suspected person to say, instantly, what the word suggests to him. The test is repeated with a great number of words, some of which, introduced in an apparently casual manner, bear directly on the crime and relate to facts which only the criminal knows. If the suspect is really guilty he is pretty sure to betray himself unconsciously. Even if he is cautious enough to modify the first response that occurs to him, he betrays himself by the slight delay thus caused, for the abnormally long interval between question and answer (which is measured to a fraction of a second) shows that he has taken time for consideration, at a point of danger.

A simpler and more objective test has recently been adopted. This test is based on the intimate relation which has been proved to exist between mental processes and the pulse and respiration. Several years ago, for example, Prof. Stoërring, of Bonn, found that feelings of pleasure and its opposite produce well-defined changes in respiration. Prof. Benussi of Graz has discovered that analogous effects are caused by lying Cards imprinted with various letters, figures, and diagrams were distributed among a class of students, each of whom was required to give a truthful description of the card given to him, unless the card was marked with a red star, in which case its recipient was required to describe it incorrectly. In either case he was watched attentively by his fellow students who, ignorant of the nature of the card, tried to guess from his manner whether he was lying or telling the truth. The observers made many mistakes, pronouncing false statements true, and conversely—a result which confirms the statement made above in regard to the difficulty of detecting falsehood by the speaker's manner and appearance.

Respiratory tests, however, gave unerring and unequivocal results. The time occupied in inspiration and in expiration was measured immediately before and after each card test, and it was found that the utterance of a false statement always increased, and the utterance of a true statement diminished, the quotient obtained by dividing the time of inspiration by the time of expiration.

The importance and scope of this discovery are obvious, for it furnishes a certain and objective criterion between truth and falsehood. Even when a clever liar endeavors to escape detection by breathing irregularly he is likely to fail in the attempt, for Benussi has investigated such cases and found that voluntary changes in respiration do not alter the result.—Abstracted from *Die Umschau*.

The Hawaiian Volcano Observatory

THE Hawaiian Volcano Observatory grew out of a lecture delivered at Honolulu in 1909 by Prof. T. A. Jaggar, Jr., of the Massachusetts Institute of Technology. The interest aroused by this lecture led a number of prominent citizens of Hawaii to subscribe funds toward founding an observatory on Kilauea, but the project remained dormant until the Summer of 1911, when the Institute of Technology sent an expedition to Hawaii under F. A. Perret, who was accompanied by Dr. Shepherd of the Carnegie Geophysical Laboratory, as a high temperature expert. The remarkable investigations carried out by this expedition, including measurements of the temperature of liquid lava, revived interest in the plan of founding an observatory, and in October, 1911, the Hawaiian Volcano Research Association was organised in Hawaii and Massachusetts. This association has provided funds for the erection and maintenance of the observatory, while the scientific work is directed by the Massachusetts Institute of Technology. Prof. Jaggar has been director of the observatory since July, 1912. The observatory issues a weekly bulletin, as well as a more elaborate semi-annual report. The Whitney Laboratory of Seismology is a branch of the work, fostered through an endowment fund presented to the Institute of Technology in 1909 by the Whitney estate of Boston. In the brief period since the observatory was established it has become a Mecca for the vulcanologists of the world, and its facilities are placed freely at the disposal of scientific visitors. Dr. Arnold Heim of the University of Zürich made a remarkable series of photographs here in 1912 for publication in Dr. Stille's "Geologische Charakterbilder." Last Winter the Hawaiian Volcano Research Association sent Prof. Jaggar to Japan to study the eruption of Sakurajima.

Rat Exterminators in England

IMPROVEMENTS in one direction invariably lead to other improvements either incidental or additional. The United States Consul at Sheffield, England, tells of the attempts made to exterminate the rats infesting the steel works and large stores of that city, and goes on to say that an opportunity will shortly occur in Sheffield to demonstrate the value of American rat exterminators. What is known as the killing shambles and the fish and meat market, located right in the center of the city, are to be pulled down in accordance with the new town planning scheme of the city authorities. When this does occur, it is recognized by the public that the homes of millions of rats will be destroyed, and articles and letters appearing in the local newspapers recently urged the corporation to do something to prevent the migration of this vermin.

Elastic Celluloid Varnish may be made as follows: Cut one ounce of celluloid into fine shreds. Add to a solution of ten ounces of acetone and ten ounces of amyl acetate and stir it well. Do not wait for it to dissolve. Cork tightly and set in a warm place. To make a thicker varnish add more celluloid, but a thin varnish is most elastic. To secure colors add aniline dyes dissolved in a little alcohol to the acetone solution.

Displacement, 27 500 tons **Speed**, 25 knots. **Armor**, waterline belt 13½-inch middle belt 10-inch upper belt 8-inch under water belt 2-inch. **Guns**, eight 15-inch sixteen 6-inch twelve 3-inch anti aeroplane guns

The British super-dreadnought 'Queen Elizabeth

An Electric Brake for Automobiles

AUTOMOBILES are growing more and more electrical every day, although their chief motive power is gasoline. We have now electric lights, electric horns, electric starters, and electric gear shifters. The latest electrical appliance for the automobile is the electric brake

About two years ago we described an electric starter in which a small motor of very high speed was used to turn the engine over The motor was far smaller than would be required to do the work if it were connected directly to the crankshaft of the engine Indeed, a gearing of 250 to 1 was interposed, permitting the motor and a flywheel it carried to acquire such a momentum in a brief interval as to carry the pistons over beyond the compression point.

This same principle is now being used to operate the emergency brake of an automobile It has the advantage that the driver of the car does not have to lean over, as in the present system, and feel around for a brake lever while keeping his eye on the road and endeavoring to steer his machine with one hand, but needs, merely, to operate a small hand lever right on his steering wheel. The brakes may be applied to any degree of pressure desired. When the wheel is absolutely locked a friction clutch comes into play, which prevents breakage of the parts. No resistance is introduced in the motor circuit, but the current is admitted to it directly Because the operation is momentary, there is no danger of burning out the motor, even though it be greatly overloaded

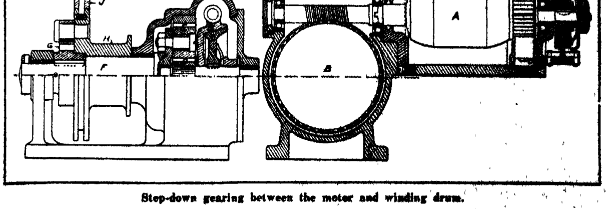
The accompanying drawings show the details of construction The motor shown at *A* drives a worm-wheel *B* This in turn, through friction wheel *C* and gearing *D*, *E*, drives the shaft *F*. On shaft *F* is a ratchet wheel *G* adapted to be engaged by pawls mounted on the winding drum *H* A cable from this drum runs to the emergency brake. Mounted on the cable drum *H* is a friction stop *J*, adapted to come into contact with the fixed stops on the casing when the brakes have been drawn up to the locked position This prevents further turning of the drum and consequent breakage of the cable By regulating the frictional contact of the stop *J* with the drum *H*, the desired maximum tension on the brake cable may be adjusted to a nicety.

Every time the brake lever is touched to admit current to the motor, the armature of the motor speeds up to an enormous speed, which is transmitted through step-down gearing to the brake drum, causing it to wind up the brake cable By successive momentary operations of the brake lever, the drum may be made to wind up its cable with a step-by-step movement until the required pressure on the brakes has been attained. Or, in case of emergency, the lever may be thrown on full, when the brakes will lock the wheel almost instantly The brake bands are preferably oiled, so as to cushion the action of this brake To release the brake, the brake lever is moved to reverse position. In place of the cumbersome controller shown in the photograph of the machine, a simple double throw switch has been devised with an automatic snap release, to prevent sparking The current used by the brake motor is no more than is used by an electric horn.

So convenient is this brake that no doubt it will be used in place of the ordinary foot brake. It is interesting to note that an electric brake of this type is being tested now on a street railway car in this city

Emergency brake lever on the steering wheel.

The brake motor and drum.



Step-down gearing between the motor and winding drum.

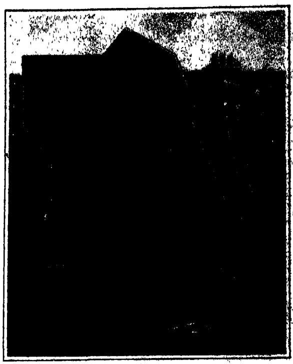
The Thalassioscope

By Dr. Alfred Gradenwitz

DR AURELIO DE GASPARIS, of Naples University, has devised an ingenious apparatus for the study of organisms at the sea bottom, which, thanks to its high magnifying power, enables all phenomena of submarine life to be watched from a considerable distance. The "thalassioscope," as the apparatus is called, will keep the image constantly in focus, thus allowing even the swiftest movements of marine animals to be followed without shifting it Its remarkable simplicity of construction reduces absorption due to refraction to a minimum.

The apparatus comprises a floating stage on which the observer is seated, and which, by means of paddles, can be moved in any direction. At the foot of this floating stage there is fixed a wide tube about four feet long and twelve inches in diameter, carrying a spur at the end. In this wide tube there moves another smaller one, to the upper part of which a large lens of about ten-foot focus is applied.

The outer tube is, moreover, provided with a binocular optical system about three feet long, comprising two lenses of about six and one half foot focus. This tube is inclined at an angle of about 45 degrees, and carries in its upper part a photographic camera and a [illegible] protective hood for the [illegible] the thalassioscope floats along the [illegible] the observer, looking through the [illegible] unwonted spectacle. He may [illegible] along the bottom of the sea, any [illegible] outside world vanishing completely. [illegible] Florideæ, red, violet, and purple, [illegible] of vivid colors, may be seen side by side with [illegible] brown and blackish Fucoids and [illegible] times assume the shape of a fan, and [illegible] as many undulating ribbons, and [illegible] massed together in bushes [illegible]. After the plains come valleys, and after these [illegible] in whose unfathomable depths swarms of fishes dart to and fro. Strange forms, of which you cannot distinguish either shape or color, dazzle the eyes by their rapid and seemingly disorderly movements. The rocks are covered by myriads of gay-colored [illegible], blended by degrees in the blue chasm, and finally disappearing altogether in unknown depths.



The thalassioscope as it appears when in use.

The spectator has the same impression as a diver, but for his feeling perfectly safe from the dangers of the sea bottom and far removed from its deathly silence which so often strikes the diver with terror.

Since everything is highly magnified, the observer is in a position to note such details as would be lost completely to the naked eye; the floating cage affords an excellent vantage ground for studying at his ease the secrets of marine biology, his specimens living in their natural element where their movements are not hampered in any way, as is, e. g., the case in an aquarium.

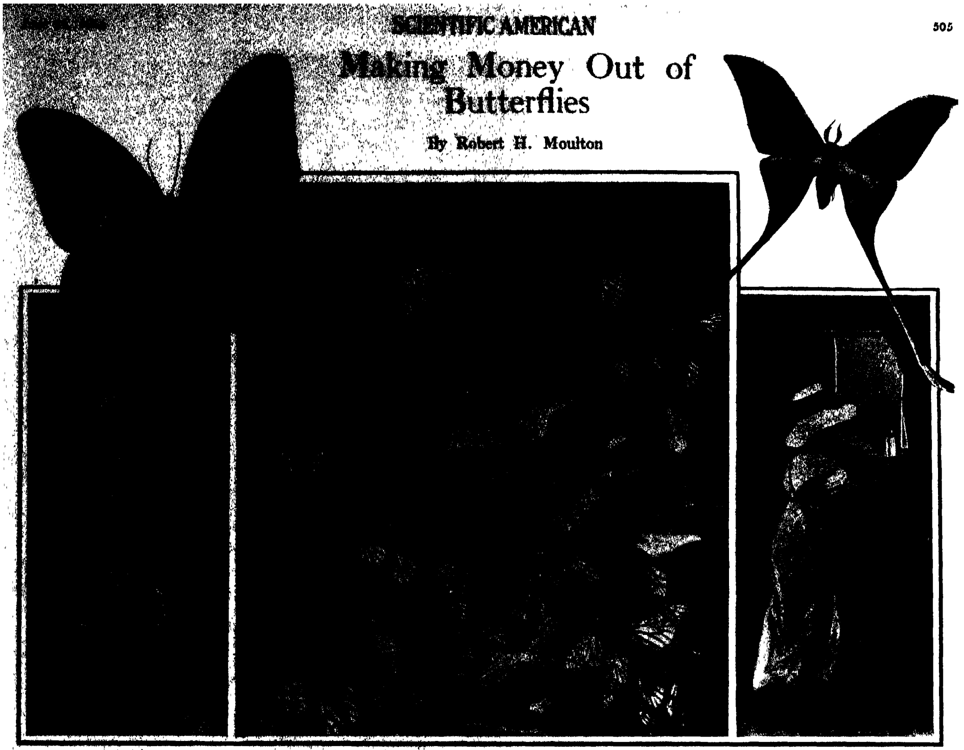
Can England Be Attacked from the Air?

THE possibility of an aerial attack upon England and other matters relating to aerial warfare were discussed at a recent meeting of the Royal United Service Institution. Col. Jackson read a paper upon defense of localities against such attacks, referring in the first place to the fleets which Germany and France will likely possess in three years, and this he thinks will be no less than forty or fifty airships of high power and an almost unlimited range, carrying a 50-ton load and traveling at an average of 60 miles an hour. No doubt the range of airships will be 1,500 miles before long. He then points out the danger of an unexpected attack upon England, and considers that the airship is far from being on the decline, or at least will not be so until armored aeroplanes prevail. Even then the airship will have manifold uses for supply of armies or transport of wounded. Soon the aeroplane will be armored so as to resist fire, and mounted by two or three men it will become indispensable in all army operations. Aeroplanes should have a machine gun on board, or a small cannon of the Pom-pom type, which had some success at Transvaal, and was recommended by the French General Langlois. At least a bomb-dropping device is needed, but he considers that a good one is not devised as yet. Then considering an attack on Great Britain—and this also applies to other places—he thinks that many points would be exposed to an attack in three years or so, but destruction of fortified places is not much to be feared, for each of these will possess defensive means. Airships hardly fly higher than 5,000 feet, so that they will be a good target for the guns. But serious damage could happen by dropping bombs upon other places, such as towns, army storehouses and factories, oil and gasoline stores, wireless telegraphy posts, and especially railroads and trains. However effective a preventive attack may be during the day, it will be difficult for aeroplanes to keep track of airships at night and prevent them from dropping bombs upon large cities such as London. He hopes that the Geneva convention as to attacks upon unfortified places would be respected, but there is no certainty about this in time of actual war, as recent experience shows, and besides, such rules did not include aircraft, so that they need to be revised. In case of bomb-dropping at night, it would be almost impossible for an aeroplane fleet to work against an airship, for the aeroplanes need some light in order to be able to steer, to see their position and to land, while the airship can sail almost without noise and without light. Only an airship fleet would be a sufficient means of defense in that case, hence the need of a sufficient fleet appears to be evident.

Pennsylvania has about seven and one half million acres of timberland, one eighth of which is owned by the State. The total value of the State's forests is 138 million dollars.

Making Money Out of Butterflies

By Robert H. Moulton



Ready for a butterfly hunt with poison bottle and net.

A wonderful group of migrating monarch butterflies.

Catching moths with bottle and lamp on a sugared cloth.

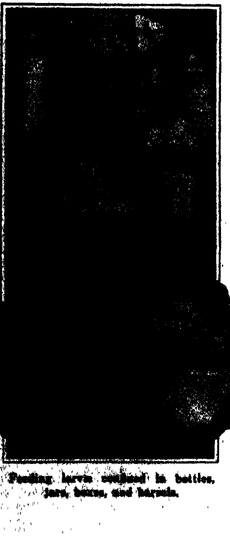
XIMENA McGLASHAN of Truckee, California, last Summer first began catching and preparing butterflies and moths for the scientific market. She was but eighteen years of age; she had no previous instruction in the work; she had no capital; her apparatus was home-made; she averaged for the season fifty dollars a week.

These combinations seem remarkable. But almost as remarkable is the fact that, though Miss McGlashan's case is exceptional, it need not be so. This successful young money-maker states that there are ten thousand places where butterflies and moths may be sold, and, of course, there are ten thousand times ten thousand localities in the United States where the insects may be snared. Every locality has its special varieties; hence, the eager demand from a market that can never be glutted, never, even, be satisfied. The butterfly business, or to speak more accurately, butterfly farming, for the raising of the winged beauties also constitutes a very important part of the industry, is open to every man, woman or child who has access to woods, meadow or back lot where butterflies are wont to gather. Few but the scientifically trained are in the business, not because a knowledge of entomology, or the science of insects, is required, but for the reason that scientific men, as a rule, being close-mouthed, are not inclined to let the public into their affairs very intimately.

The first season's work netted her $520. Twenty thousand eggs, larvæ (or caterpillars) and pupæ (larvæ in the cocoon stage) of butterflies and moths were also stored away for the Winter, a "stock" with which to make a magnificent start in the Spring.

The original apparatus was as follows: Several wide-mouthed bottles, each containing a small quantity of cyanide, in a leather case to be strapped to the shoulder; a few paper boxes; a butterfly net; a pair of delicate forceps. Cyanide may be bought in cake form at 30 or 60 cents a pound. A piece of No. 9 wire, a light bamboo rod, a few cents' worth of gauze, and there is the net. Forceps are to be had for [illegible] cents the pair. Not much capital required for a start in so lucrative a business, was there? With this simple equipment she sallied forth upon her first conquest of the butterfly lands. Cyanide is both a deadly poison and a harmless [illegible]—harmless to the butterflies, at any rate, if they are not permitted to remain corked up with it [illegible]. Each specimen Miss McGlashan [illegible] transferred to the bottle, the quicker [illegible] to injure itself by its struggles [illegible] through the gauze. As she worked, every few minutes she carefully sorted over her catch. Males of the commoner species in perfect condition she let perish, with the purpose of disposing of them in the market at once. Only the absolutely perfect specimens will sell. Dealers can never be imposed upon; their eyes are far sharper than those of any amateur No half-rates for slipshod work: it is perfection or nothing that is demanded in this business. Those males slightly bruised or with wings battered, were reserved for breeding purposes, as were females. Miss McGlashan had already arranged with a dealer to take her mounted specimens at a flat rate of 5 cents each. From the very first, therefore, she began to make money.

Feeding female moths and butterflies while they are laying eggs in boxes and paper bags.



Feeding larvæ confined in bottles, jars, boxes, and barrels.

The processes, if intelligently studied, are relatively simple, deft touch and painstaking care being the chief requisites Cork-lined boxes, cork linoleum, which, by the way, is a good deal the cheaper and every bit as good, or insect cork may be used to secure the cyanide-asphyxiated insects safely for shipment. For this purpose special pins, which sell at $1.25 per thousand, or less in larger lots, must be used. Any other sort of pins won't do at all. They are not fine enough, and will utterly spoil the thorax of the insects through which they should always be put in mounting. Another pair of forceps larger than the ones used in ordinary handling of the butterfly or moth must be employed, to take hold of the pin from beneath the insect and force the point firmly down into the bed of cork. If fingers should so much as even slightly brush or touch a specimen, the chances are pretty certain that it is irrevocably ruined. One fact, a very important one, too, must be strictly borne in mind by the shipper: he should be certain the dealer who has agreed to make purchases of him is fair and reliable. Miss McGlashan's prisons for her captives probably were the least expensive part of her inexpensive equipment. These were the little paper boxes previously mentioned. As she sorted her booty of the meadows she transferred each of the living to its separate box. These little box prisons were but temporary. On the captives being taken home, other arrangements for keeping them had to be made. Of course, the purpose in preserving the females alive is to secure eggs and, ultimately, more butterflies. This method naturally enables the butterfly farmer to obtain a much larger and more perfect "crop" than he would otherwise. But it is rather difficult to induce the female to lay unless conditions are entirely satisfactory, though moths are not at all particular in this respect. Most butterflies in captivity prefer to lay their eggs in gauze bags; all insist that a piece of their special

(*Concluded on page 511.*)

Hearing Ourselves as Others Hear Us

IT is a well-known and frequently observed fact that many singers and performers on musical instruments exhibit a degree of complacent satisfaction with their own efforts, which is not at all commensurate with the amount of pleasure they have given their audience. But the exaggerated view they form of the musical value of their achievements is not entirely due to that vanity to which our poor human nature is so prone. They do not, as a matter of fact, hear themselves as others hear them. This is particularly the case with a singer. A singer produces and hears a note at the same time, the sound being conveyed through the Eustachian tube of the ear. The *external sound*, the sound heard by the audience, is not, in the ordinary way, heard by the singer at all.

Mr. Donald McIlardy, a voice specialist of many years standing, has invented an apparatus to obviate this disadvantage under which all singers and instrumentalists have hitherto labored. The apparatus is extremely simple and consists of a half-sphere made of metal, connected to a long flexible, metallic tube. The tube terminates in two branches, the ends of which fit in either ear. The sound produced by the performer, after impinging on the open half-sphere, travels down the metallic tube to the performer's ears. The sound heard by the performer in this way corresponds exactly to the effect produced on an audience.

Although so simple, the apparatus in its present form is the outcome of a good deal of experiment. Various-shaped openings for the metal receiver have been tried, but the half sphere opening is the only one which gives satisfactory results. Various materials have been employed in the construction of the connecting tube, with the result that the metal at present employed has been found to possess distinct advantages. As was to be expected, it was found that a rubber tube gave very poor results.

The present writer took the opportunity of playing a piano solo to a small audience, first with and then without the apparatus, and the audience were unanimous in declaring that the second performance was distinctly better, although to the writer they sounded identical.

How to hear yourself play the piano and sing.

"Marble Light"

By Our Berlin Correspondent

IT has been known for a long time that marble in very thin sheets is *translucent*, and that colored marble sheets give the most striking effects. A German engineer, Mr. Hermann W. Engel, of Hamburg, by a *special* polishing and impregnating process, has, however, succeeded in endowing marble slabs of considerable thickness (1/10 to 3/4 inch) with a transparency far superior to that of opal glass. After being polished on both sides, these marble sheets are impregnated with diverse oils, at high temperatures, under heavy pressure. This process is not only less costly than [illegible] only a few thousandths of an inch in thickness, but insures far greater solidity. The color effects of such marble slabs, on account of the greater thickness, are much more beautiful than in the case of the thin layers. Skylights of colored marble have been provided aboard some German steamers, and, when lighted at night by electric incandescent lamps, produce effects of remarkable beauty.

Some most interesting tests have been made by Dr. Voege at the Hamburg State Laboratory, which go to show that light passing through this marble possesses many striking qualities, and is equally commendable for economic and hygienic reasons.

From comparative tests on opal glass and impregnated marble plates, respectively, it is seen that the latter possess far greater transparency. Moreover, they are lighted uniformly up to the edges, and when inspected side by side with opal glass, appear perfectly white. Impregnated marble is especially efficient if an electric lamp arranged within a reflecting box be used as the source of light, which source can be closed by a marble slab or milk-glass plate. Whereas the former only absorbs about 20 per cent of the total radiation, the latter, in fact, holds back as much as 40 per cent. In spite of its greater transparency, marble is fully equal to milk-glass, as far as its power of absorption is concerned. The most striking feature of marble light, however, is its remarkable softness and pleasing effect.

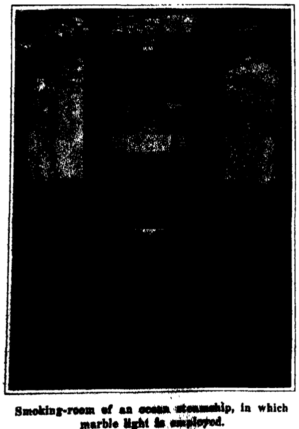
A device whereby the players of wind instruments can sustain tones indefinitely.

The central picture shows the course of the air-current from the mouth-piece of device *A*, at the corner of mouth, around the structure of the mouth to the mouth-piece of instrument *B*, at the center of lips. At the moment of the player's intake of breath through the nostrils *C*, the entrance to the lungs from the mouth is automatically closed by the pressure of the base of the tongue *F* against the soft palate *D*. The stop-valve on the device *E* prevents the re-entrance of air into the tubing of the device once it has entered the mouth; therefore, the only outlet for the air is by the natural course, cleaving to the roof of the mouth *G*, striking the soft palate *D*, and working backward along the surface of the tongue *F* to the mouth-piece of the instrument *B*. Meanwhile the air admitted to the player's lungs enters only by way of the nostrils *C*. He may even breathe out through the nostrils and still indefinitely sustain the tone of the instrument by the air-current which the pedally-operated bellows supplies. That air-current is warmed and moistened to the degree of the human breath by an incandescent bulb and immediately adjacent water-chamber contained within the bellows structure.

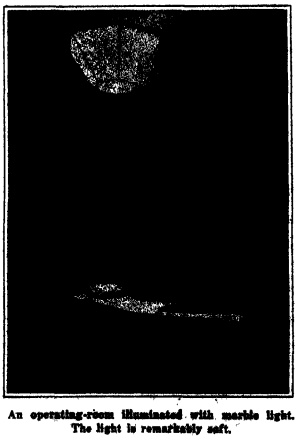
Artificial Lungs for Bandsmen

By Harry Chapin Plummer

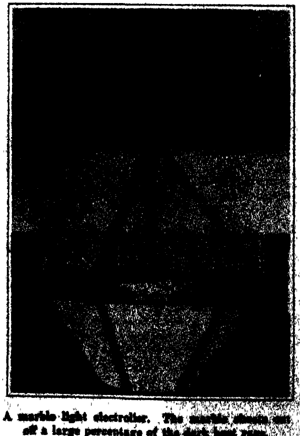
TO provide an efficient physical means for fulfilling the superhuman demands imposed upon wind instrumentalists by the great symphonic and operatic scores of Richard Strauss, Wagner, Brahms, d'Indy, and the modern school, a new tone-sustaining apparatus has been devised by Bernard Samuels, a native of Paramaribo, Dutch Guiana, who is at present first flutist of the Royal Opera at Schwerin, in Germany, and chamber musician to the Grand Duke of Mecklenburg-Schwerin. The new device consists of a foot-bellows having a water-chamber with incandescent bulb and a length of rubber tubing fitted with a stop-valve and mouth-piece, all simply attached, for the convenience of the player, to the instrument that is being played, but in no sense forming a part of the instrument. By means of the water-chamber and electric-light bulb, the air forced through



Smoking-room of an ocean steamship, in which marble light is employed.



An operating-room illuminated with marble light. The light is remarkably soft.



A marble light electrolier. The marble sheets cut off a large percentage of the dark heat rays.

[illegible] pressure of the foot upon the bellows is such [illegible] and [illegible] to meet the degree of the human breath and is transmitted to the mouth by the rubber tubing. It enters through the mouthpiece at the corner of the mouth and, performing the natural circuit of the mouth, passes out through the mouthpiece of the instrument, at the center of the mouth. So, when the performer is drawing breath through the nostrils, the current of air started by his foot sustains the tone upon which he is engaged. It will matter little whether that tone be a single note or an elaborate cadenza—the pressure of the bellows will sustain it indefinitely, if desired. Although the air from the bellows is carried into the mouth, the stop-valve within the tubing prevents the entrance of any air into the bellows.

Composers will now be afforded a well-nigh unlimited scope in writing for brass and reed instruments. Already Richard Strauss has specifically designated the device in more than one passage of his "Festival Prelude."

The device is now well established in the principal symphony and opera orchestras. The Royal Opera of Berlin, of which Dr. Strauss is the director, was one of the first representative institutions to have the entire brass contingent of its orchestra equipped with the apparatus.

Just what aid the device renders to important musical performances may be judged from the fact that it was employed in the recent rendition of the "Nibelung Ring" cycle of music-dramas by Wagner at the Metropolitan Opera House, and it was the first occasion at that theater when the full strength of the horns could be employed in certain passages simultaneously. In the prelude to "Das Rheingold," for example, the tubas are called upon to hold a tone for ninety bars. Until now this has been a physical impossibility for the individual player, who has had to take breath after every three or four bars. Now, however, all the players can sustain the tone for the full ninety bars. Similarly, in the "Dragon music" of "Siegfried," the tuba will be able to sound its stentorian and raucous bass tones without having to chop and break the phrases, as hitherto.

James T. Allen

ON May 26th James T. Allen died at Washington, D. C., from a complication of troubles. He was a veteran examiner in the Patent Office, having been appointed September 18th, 1868, from the Twenty-sixth Congressional District of New York, making his service nearly forty-six years in length. He was a careful and conscientious worker, with a wide acquaintance and friendship among patent attorneys. During his service he compiled digests of plows, seeders, and planters, harrows, grain drills, and air and gas engines, and for a time edited monthly periodicals relating to these digests. These publications were in wide demand, many having gone to Germany and other European countries. For forty years he had charge of the important class of seeders and planters, and served the Government and inventors with entire satisfaction.

Decisions on Patents

THE Jenner patent, 804,726, for a candy-pulling machine has had its claim 1 held invalid and its claims 7 and 8 valid and infringed in Hildreth v. Lauer, & Suter Company; and in the same case the Dickerson patent, 881,501, for a candy-pulling machine has had its claim 1 held valid and infringed and claim 2 valid but not infringed. In Lewis Blind-Stitch Machine Company v. Arbeter Felling Machine Company, the Lewis patent, [illegible], for a blind-stitch sewing machine has been held valid but not infringed. The Lane design patent, [illegible], for a design for a piano case, has been held valid and infringed in Bush & Lane Piano Company v. [illegible]. The Parsons patent, [illegible], for pneumatic tire casing, has been held valid and infringed in Parsons [illegible] Company v. E. J. [illegible] Company. In Crown Cork and Seal Company of Baltimore City v. Sterling Cork and Seal Company, the Painter patent, [illegible], for a machine for automatically sealing bottles, has been held not infringed, while the Painter and Hawkins patent, 842,978, for an apparatus for feeding crowns to a bottle-sealing machine, has been construed and is limited, held not infringed.

Notes for Inventors

A Self-Threading Shuttle.—A. Meunier of Taunton, Mass., in patent No. 1,093,718 presents a self-threading construction of shuttle which does not result in an objectionable weakening of the shuttle and can be readily applied to or embodied in shuttles now in use.

A Mail-Collecting System.—Samuel C. Cox of Washington, D. C., has patented an improvement in mail collecting in which the collecting vehicle co-operates with the mail box. The mail is delivered directly from the box into the receptacle of the vehicle without intermediate handling.

The Label and the Laundry.—Joseph French of Woonsocket, R. I., has secured patent No. 1,093,985 for a label-attaching improvement in which the label is fastened temporarily to the article by a thread which, while it holds the label to the article during the required treatment, can be easily withdrawn to detach the label.

Electric Lamps to Indicate Liquid Level.—Patent No. 1,093,745 has been issued to John A. Turner of Washington, D. C., in which the level of liquid in a tank is indicated electrically through the aid of a vertical series of lamps whose individual circuits are opened and closed by the rise and fall of the water in the tank, thus showing visually the level of the water in the tank.

A Re-Winder for Music Sheets.—Patent No. 1,093,813 was issued to Frank C. White of Meriden, Conn., assignor to Wilcox & White of same place for an improvement in music playing instruments, having for its object to stop the forward travel of the note sheet at the end of the composition, re-wind the sheet on its spool and to finally stop the machine when the sheet is fully re-wound.

Secret Photograph as an Aid to Subsequent Identification.—In patent No. 1,094,073 Alfred Ilg of Zürich, Switzerland, provides for photographing a person without his knowledge. He time stamps and dates the photograph so it may be subsequently used for identifying the person. The invention is especially adapted for use by police and pawnbrokers.

The Water-proofing of Concrete.—Richard K. Mead of Roland Park, Md., in patent No. 1,092,933 has patented a process and concrete composition wherein waterproof qualities are imparted to cement by adding to the cement a powdered filler whose particles are oil-coated so that when made into concrete or the like it will be impervious to water.

Using Paper to Indicate Broken Rails.—In patent No. 1,092,986 Joseph H. Gardside of Philadelphia, Pa., provides strips of paper attached to railroad rails throughout their lengths. These strips will be broken by a passing train if the rail be defective and thus plainly indicate to the track-walker the defects in the rail.

An Elihu Thomson Turbo Ship-Steadying Patent.—Elihu Thomson of Swampscott, Mass., assignor to General Electric Company, in patent No. 1,093,159 utilizes the rotating parts of the turbo generator as a great gyroscope to steady the ship and reduce her rolling, the turbo generator having a vertical shaft.

Protecting the Hat from Rain.—Christine Mullaney of New York city has patented an emergency covering for hats, which cover is made of waterproof paper and can be secured to the hat by the customary hat pins employed to hold the hat on the head.

Preventing the Splitting of Railway Ties.—A method of preserving railway ties has been patented in No. 1,093,230 to William E. Williams of Chicago, Ill. The tie is compressed and a metal band is secured tightly around the tie at the compressed places with a view to preventing the checks and splints induced by the spikes and the slowly developed splits and cracks resulting from the traffic.

Two Moving-Picture Apparatus Patents.—Adolph F. Gall of West Orange, N. J., assignor to New Jersey Patent Company of West Orange, has secured patents Nos. 1,092,905 and 1,092,906, the first providing a screen and operating means therefor for protecting the moving-picture film from the heat emanating from the projecting lamp, while the second patent controls the passage of light through a projection aperture of the lamp house in such manner as to insure the closing of the projection aperture of the device when the latter is in any position except the projecting one, and will uncover the aperture when the device is moved into a projecting position.

A Patent to Tom Johnson.—Margaret J. Johnson, as administratrix of Tom L. Johnson, deceased, of Cleveland, Ohio, has secured patent No. 1,090,213 for a high-speed railway in which a stationary element along which the truck is movable has a portion above the truck and means for creating both a tractive and lifting effect on the truck by which a magnetic field is created which passes between the stationary element of the truck and such field is distorted in the direction that the truck is adapted to move.

Two Patents to Charles Francis Jenkins.—Charles Francis Jenkins, the well-known inventor of Washington, D. C., has secured patent No. 1,089,645 for an aeroplane engine in which a closed crankcase has opposite depressions, receiving cylinders, and is revolubly mounted upon a fixed axial crankshaft, piston structures passing through openings in the crankcase with an aeroplane propeller carried by and rotating with the crankcase. He has also secured patent No. 1,089,646 for a motion-picture camera in which a lens moves in an endless path and carries with it a portion of a film, which portion is exposed while the lens moves through a portion of its path, the movement of the lens through another portion of its path bringing a fresh portion of a film into its axis.

Preparing Mail Matter for Posting.—Patent No. 1,090,499 to John W. Poller of Takoma Park, Md., assignor to Molyneux Mailing Machine Company of Buffalo, N. Y., is for a machine which folds up a sheet of paper in flat form, removes an envelope from a pack of envelopes, inserts the sheet of paper in such envelope after opening and positioning the envelope, suitable means being provided for directing the sheet into the open envelope.

Correcting the Drawings of Patent Applications.—An order has recently been issued by the U. S. Patent Office, having for its purpose to stop the constant mutilation of the Office records. Hereafter corrections and alterations of the drawings of pending patent applications will be made only by the draftsmen employed by the Patent Office, a reasonable charge to be made by the chief draftsman for such corrections as may be necessary.

A Charles Steinmetz Patent.—In patent No. 1,088,740 to the General Electric Company as assignee of Charles P. Steinmetz, there is presented a method of producing an arc in a transparent chamber between terminals, one of which is vaporizable at low temperature and the arc being colored by the addition of a chemically active metallic substance while the enclosing chamber is protected from injury by neutralizing the chemical activity of the metallic substance.

A Motor Field Structure which Operates as a Pulley.—Ethelbert M. Frazer of Yonkers, N. Y., has patented an electric motor particularly adapted for use in connection with a tractor elevator. The motor has a stationary armature and a rotatable wheel structure which is encircled by the armature and is so constructed that it can be used as a pulley to operate a flexible driving connector.

Legal Notes

New Combination of Old Elements.—In United Gas Improvement Company v. Gas Machine Company, Fed. Rep 211-672, the court has held that a new combination of old elements, which, by their co-operative action, produce a more beneficial result, amounts to invention, which is not negatived by the fact that such co-operation requires the mediation of an operator. Also in the same case it was held that where a patent contains description of only one form of a thing which will perform the same office in other forms, the court will apply the general rule that the description covers all equivalent forms and the form described will be treated only as the one preferred

New Use of Old Material.—In O'Brien-Worthern Company v Stempel, Circuit Judge Sanborn said "But the application of an old device to a new one is not always or generally even patentable It is only when the new use is so recondite and remote from that to which the old device has been applied or for which it was conceived that its application to the new use would not occur to the mind of the ordinary mechanic skilled in the art that there is invention in the conception of its application to the new use, and the old use fails to limit the claim of such an application " Along the same line Circuit Judge Lacombe in Archer et al v Imperial Machine Company, said "Sometimes it is true a change of material will produce a novel and unexpected result which might evidence invention "

'Supreme Court Decision on Ten-Year Clause Trade-Marks.—Some interesting matters are included in the decision of the Supreme Court of the United States, the opinion being rendered by Mr Justice Hughes, in the case of Thaddeus Davids Company v. Davids & Davids, trading as Davids Manufacturing Company The registered trade-mark was the surname "Davids," registration being secured under the provisions of the ten-year clause of the act. The court said that as the mark consists of an ordinary surname, it was not the subject of exclusive appropriation as a common-law trade-mark, and the applicant who by virtue of actual and exclusive use is entitled to register his mark under this clause (the ten-year clause) becomes on due registration the "owner" of a "trade-mark "

Some Adjudicated Patents.—In the Ney Manufacturing Company v G A Swineford Company, the Taylor patent No 486,812 for a track for hay carriers has as to claim 1 been held void as covering a broad combination of which the patentee never claimed under oath to be the originator or the inventor, and the Anderson and Holstein patent No 683,425 for process of making fabric-covered ornaments was held not infringed in Holstein v Seeland Ornamental Company; the Rhodes patent No. 777,488 for a fish bait or lure was held valid and infringed in William Shakespeare, Jr. v. Enterprize Manufacturing Company, and the Carter patent No 777,714 for a culvert was held not infringed in Carter v Burch Plough Works Company The Niez reissue patent No 13,163 (original 916,361) for a disk harrow was held valid and infringed in Bucher & Gibbs Plow Company v International Harvester Company

The Term of Design Patents.—Heretofore it has been the practice to hold applicants for design patents to the election of term, whether three and a half or seven years, specified in the application, but Commissioner Ewing has with the approval of the Secretary of the Interior amended the Patent Office Rule of Practice to permit the applicant who may in his application request the issue of the patent for one of the shorter terms to amend his application at any time before the allowance of the application, upon the payment of an additional Government fee, and to request the issue of the patent for the longer term, so that if the application originally elects a term of three and a half years or seven years, the applicant may extend the term to seven years or to fourteen years as may be desired.

RECENTLY PATENTED INVENTIONS

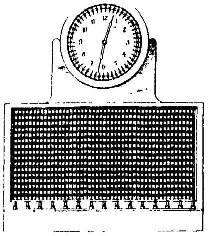
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

NECKBAND FOR SHIRTS.—J. H. FUNK, 546 W 156th St., New York. The invention provides a neckband cut so as to have an overlapping end portion for thickening the band at the end carrying the button, so as to prevent pressure of the button against the neck. The design of the neckband is such as to reduce the movements in the manufacture thereof to a minimum, and at the same time provide button guards both at the top and back.

Electrical Devices.

ANNUNCIATOR SYSTEM.—T. A. HAUGAARD, care of B and B Dept., U P R R, Cheyenne, Wyo. To do away with the use of a "call sheet" by hotel clerks whose failure to record the desired call or to make the call after entering it, has led to much distress and loss of time to travelers, Mr Haugaard has invented this system, in which the traveler may see for himself that the plug is in the annunciator, when he may be assured that he will be awakened at the desired time. Its capacity is unlimited and it can be installed without much expense beyond that of installing the ordinary annunciators.



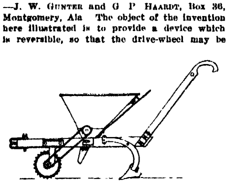
AUTOMATIC CALL SYSTEM FOR GUESTS OF HOTELS

CONNECTING CLIP FOR ELECTRICAL CONDUCTORS.—J. G ELKIN, care of Elk Manufacturing Co., 68-72 E 131st St, New York. The clip here illustrated may be securely fastened to insulating conductor wire, enabling it to be quickly and conveniently attached to or detached from a binding post or the like. It consists of a pair of spring-pressed jaws pivotally connected and a clamp on the pivots of the jaws, adapted to engage the bare end of the wire conductor, this clamp consisting of a hollow screw with tapered bore adjustable upon tapered clamping members, thereby providing a quick-action gripping of the wire.

CONNECTING CLIP FOR ELECTRICAL CONDUCTORS.

Of Interest to Farmers.

REVERSIBLE FERTILIZER DISTRIBUTOR.—J. W. GUNTER and G P HAARDT, Box 36, Montgomery, Ala. The object of the invention here illustrated is to provide a device which is reversible, so that the drive-wheel may be placed either at the front or at the rear of the plow blade, thereby permitting the fertilizer to be deposited and plowed under, or to be placed in the furrow and covered by the follower. The device is provided with a feed which may be regulated as desired. Means are provided for agitating the fertilizer and for forcing it toward the feed opening.



REVERSIBLE FERTILIZER DISTRIBUTOR.

FENCE STAY.—J. A. NICKOLAUS, R. F. D No. 3, Mount Pleasant, Iowa. The fence stay consists of a single strand of wire so formed as to provide an anchoring element at one end, which may be readily and quickly secured in position in connection with an erected fence, in order to support efficiently those wires between the posts of the fence, which are otherwise likely to sag.

TRACTION ENGINE.—F. HECKMAN, Maria Stein, Ohio. The traction engine has two traction wheels on a divided axle connected by differential gearing and driven by an internal combustion engine. Normally the traction engine has no rear wheels, as it is adapted to be coupled to the wagon or agricultural implement that is to be hauled. However, means are provided for supporting the rear of the tractor on supplementary rear wheels, if so desired.

SWIVEL CONNECTOR.—G. W. OAKES, care of Pittsburgh Plate Glass Co., Crystal City, Mo. This invention relates generally to swivel connectors adapted to be placed in electrical conductors in order to prevent tangling of the conductors in moving about apparatus to which they are attached. It consists of a pair of swivel terminal members to which the conductors are connected and about which there is a casing of insulating material.

MAGNETO.—W. CASEY AND I. LESSES, 384 Brock St, Kingston, Ontario, Can. Exposed wiring is done away with in this magneto and the mechanism is made waterproof. The high-tension conductors are short, thereby lessening the chances of grounds and short-circuits. The parts are so arranged that the current is delivered at maximum intensity over a long range.

ELECTRIC HORN SWITCH.—J. E FOULKS, JR., 1324 Dean St, Brooklyn, N. Y. In order to permit of turning on the electric current to an automobile horn or siren without removing the operator's hand from the steering wheel, the present invention provides a switch in the form of a ring secured to the steering wheel. By pressing the ring toward the wheel, at any point, one or more contacts are made, closing the circuit of the electric horn.

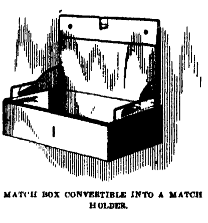
HOUSING FOR ELECTROMAGNETS.—E. GEGENBACH, care of Duplex Electric Co., 514 W. 57th St, New York. The invention relates particularly to ironclad housings for electromagnets, which will not only provide greater protection for the winding of the electromagnet, but also greater efficiency of operation. The housings are made of sheet metal bent to suitable form, with certain portions co-operating with the armatures of the electromagnets.

Of General Interest.

ENVELOPE.—G. SCHNITZLER, 100 Amerman Ave, Arverne, N Y. The principal objects of this invention are: To provide an envelope having a tearing section reinforced to provide a uniting member, the structure of which is unbroken; to provide means for preventing the introduction within the tearing area of the letter or enclosure when deposited in the envelope, and to provide means of the character mentioned readily and cheaply applicable to envelopes constructed in accordance with the present invention.

CLEANING METAL SURFACES.—C. H. THOMPSON, Harrington House, Amblecote, Stourbridge, England. The process consists in placing articles without metallic connection with the electrodes in a bath of any suitable chlorid, sulfate, or nitrate solution, preventing the articles from contacting with the electrodes, arranging said articles in series with each other and the electrodes, and passing an alternating-current through the bath, the current, by this arrangement of articles and electrodes, passing through the articles in succession.

MATCHBOX.—H. W. GASKILL, Columbus, New Mexico. The device here illustrated consists of a box containing matches, which is so constructed that it may be used as a match safe or holder. The top of the box may be extended and secured to a wall, while braces are provided for securing the body of the box at right angles to the top portion.



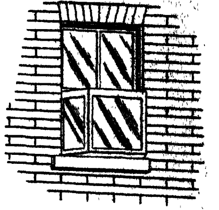
MATCH BOX CONVERTIBLE INTO A MATCH HOLDER.

ERASER HOLDER.—C. E. MOON, Box 972, Oxnard, Cal. Among the objects of the present invention are: To provide a simple, inexpensive, and strong eraser holder which is neat in appearance, has no projecting portions which will interfere when it is placed in a pocket, which can be easily placed on a pencil or removed from it, and which will permit the consumption of substantially the entire eraser.

PLASTIC COMPOSITION.—J. E BECK, Sunnyvale, Cal. This plastic composition is adapted to be used in lieu of ordinary plaster walls and ceilings, or for flooring, pavements, plaster boards, shoe leather, trunks, suitcases, drums, barrels, boxes, etc. It consists of straw digested in lye, and subsequently pulped, mixed with flour, zinc chlorid, and coloring matter.

BOTTLE GUARD.—C. [illegible], Box 27, Douglas, District of Alaska. The invention relates to non-refillable bottles and provides means for preventing the insertion of a tool or implement. This means consists in a web that runs across the neck of the bottle with an opening in the web and a downwardly-extending arched cap over the opening. A [illegible] rib forms a further obstruction to the introduction of a tool.

WINDOW.—J. R. BOILEAU, Minocqua, Wis. The invention provides means capable of being applied to an ordinary window to convert it into an extension or bow window, so as to permit the occupant of a room to see laterally as well as directly outward. The device may be inclosed by a perforated covering in warm weather, to prevent the entrance of insects, dust, and the like, or with an imperforate, transparent covering, in Winter, to prevent the entrance of cold air, without obstructing the view.



AN EXTENSIBLE BOW WINDOW.

UMBRELLA.—C. SCHMIDT and A. HIRSCHWITZ, 1342 St. Bernard Ave., New Orleans, La. The invention has for its object a provision of simple and inexpensive means for connecting the ribs and stretchers of the umbrella to the stick in such manner that they may be easily detached and removed for the purpose of repairing, without necessitating the removal of the cover or disassembling the elements of the umbrella.

PROCESS FOR MOLDING PLATES.—A. J. JARMAN, care of J. J. Travers, 45 Brittam Ave., Elmhurst, Long Island, N. Y. The object of the invention is to produce an inexpensive light and reliable molding plate for half-tone or line work in typographic or intaglio printing, which plate will receive all the impressions of a suitable matrix, no matter how fine, without warping, and give a good hold to the printing ink.

FURNACE DOOR OR CLOSURE.—J. B. PHILLIPS and J. A KAPLAN, 523 Avington Ave., Zanesville, Ohio. This invention relates to the doors or closures of smelting furnaces where exceedingly high heat is generated. As heretofore constructed these doors are apt to burn out frequently. Accordingly, the present invention provides an all-refractory closure, consisting of a single slab of firebrick or the like with a novel holder constituting a gripping and suspending means for the refractory closure.

Hardware and Tools.

BOLT AND NUT LOCK.—D. D. TULLOCH, 266 Market Street, Newark, N. J. The invention provides an improved bolt and nut lock in which a bolt of uniform dimensions with respect to the standard size bolt used, is designed for co-operation with a nut of special design in that it is increased in thickness and counterbored to receive a plug attached to the bolt and forming means to lock the nut to the bolt against rotation.

Heating and Lighting.

TAKE-DOWN COOK RANGE.—G. N. FRASER, Eugene, Oregon. The present invention, which is an improvement on a previous take-down cook range invented by Mr. Fraser, consists of four sections, namely a firebox section, a flue section opposite to and facing the firebox section and intermediate upper and lower sections. All four sections may be readily and quickly assembled and taken apart, and when free from one another may be conveniently stored in a minimum space.

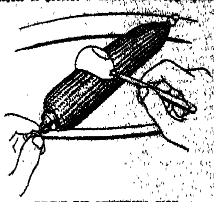
TAKE-DOWN COOK RANGE.

HEATING APPARATUS.—J. McGUIAN, Savannah, Ga. The furnace has heating chambers connected by pipes with a delivery flue for delivering the [illegible] and a [illegible] bers and [illegible] suction thereon [illegible] ing chambers, to draw the [illegible] them and into the flue.

GAS TUBE COUPLING.—[illegible] catur and Walter [illegible]. The invention relates to a [illegible] conducting gas from a [illegible] lamp or stove. It provides [illegible] ler arranged for convenient [illegible] gas nipple without danger of [illegible] dentally detached.

Household Utilities.

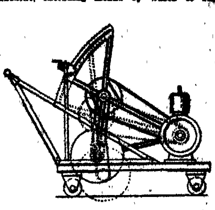
CORN BUTTERER.—H. M. [illegible], [illegible] er St. (Room 504), New York, N. Y. The invention relates to tableware, and has for its object to provide a device for evenly spreading butter on an ear of corn. The device consists of a handled bowl adapted to contain butter and a concave perforated cover adapted to fit upon the peripheral face of an ear of corn.



DEVICE FOR BUTTERING CORN.

Machines and Mechanical Devices.

MACHINE FOR CUTTING PAVING.—GREGORY PERKINS, 505 West 21st St., Los Angeles, Cal. Mr. Perkins' present invention relates to a machine for cutting asphalt and other paving through the use of a power driven circular saw, his object being to provide a machine, including means by which to support a circular saw in such manner that it may be adjusted toward and away from the ground and held in selected position for cutting the paving or other material to a desired depth.



MACHINE FOR CUTTING PAVING.

BOBBIN-STOP.—C. NORDELL, Gilbertville, Mass. The invention provides a means for stopping the bobbin when "piecing up." The bobbin is mounted upon a shell which has frictional engagements with a rubber clutch member engaging the driving pulley. To stop the bobbin the shell is raised out of engagement with the clutch by means of a lever, and is stopped by frictional engagement with a fixed yoke.

THREAD-CUTTER.—J. A. DOWD, Box 411, Fall River, Mass. This thread cutter is adapted to cut threads on pipes and form spaced threaded portions. The cutter is provided with a threaded peripheral surface with the thread or spurs at different distances from the center of the cutter so as to cut straight or tapering threads on the tube or bar in a continuous operation.

DRILL.—J. T. CURNOW, Palatka, Mich. The principal objects of this invention are to provide means for clearing a drill hole while drilling, to introduce a water jet for washing the hole and cooling the drill point, to utilize the power applied to the drill for water-jetting the drill hole and to provide means for controlling the supply of water to the hole.

AMALGAMATOR.—S. BUSS, Greenwood, Cal. The invention provides a device within the means of the private miner, although capable of embodiment in apparatus of large size, for the treatment of gravels to recover the "rusty" gold formerly lost, owing to the formation of rust on the gold bearing material which resisted the amalgamating action in the operation of the ordinary apparatus.

APPARATUS FOR MANUFACTURING OBJECTS FROM PLASTIC [illegible].—O. EBERHARD, Heidelberg, [illegible] many. The apparatus relates [illegible] ture of soap, sweets, and the like [illegible] number of diversely colored [illegible] through a die to [illegible] in the mixing chamber [illegible]

[illegible]

[illegible] MACHINE.—G. D. [illegible], [illegible] A machine for vending packages preferably of [illegible] shape is provided by the present invention. The hopper in which the packages are contained has its outlet normally closed, but when a coin is placed in the slot, the outlet becomes operative, and upon operating means manipulated from the outside of the casing, the package is delivered from the hopper.

FRUIT WASHING MACHINE.—A. R. Stevens, care of Gulf Iron Works, Tampa, Fla. The invention provides a fruit washer which has comparatively few moving parts and therefore is not liable to get out of order easily. It is adapted particularly for washing oranges or lemons and comprises a means for rotating the fruit so as to expose all parts to the cleansing action.

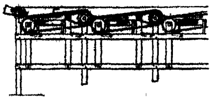
FRUIT SIZER.—A. R. Stevens, care Gulf Iron Works, Tampa, Fla. The object of this invention is to provide a device by means of which fruit may be graded into sizes according to the largest diameter of the fruit. A further object is to provide means for adjusting the parts of the sizer so as to vary the sizes of the fruit deposited at any one point.

BOX PRESS.—A. R. Stevens, care Gulf Iron Works, Tampa, Fla. The present invention relates to box presses utilized to press and hold the cover on a fruit box while it is being nailed and strapped. The invention provides simple and inexpensive apparatus in connection with such a press which will be durable and effective in use and which embodies certain novel features of construction.

SAWMILL.—R. H. Orr, R. F. D. Route 3, Sebastopol, Cal. Mr. Orr's invention is an improvement in sawmills, and has for its object to provide a simple and easily operated machine in which the saw is capable of a large variety of adjustments, both when in horizontal and when in vertical position.

TORPEDO STEERING MECHANISM.—J. J. Dallier, Great Lakes, Ill. Among the principal objects of this invention are: To provide means for maintaining a torpedo on a relatively straight course, to provide an operating mechanism for a steering gear, to effect the above-mentioned purposes easily and positively, and to provide operating means for the steering rudder, said means being removable from service position, without loss of time and without undue effort.

MACHINE FOR GRADING FRUIT.—F. C. and C. M. Jaquette, R. F. D. No. 1, Grand Junction, Colorado. An improvement in fruit graders is provided by the present invention, which has for its object to furnish a mechanism adapted for grading fruit as it is moved by endless carriers, and wherein a series of carriers is provided, each arranged to deliver from the machine all fruit below a certain size.



MACHINE FOR GRADING FRUIT.

COMBINED BORING MACHINE AND LATHE.—H. J. Wyatt, Longbranch, Washington. The object of this invention is to provide an improved boring machine and lathe arranged to permit of convenient use for boring or turning purposes, the machine being provided with a spindle capable of receiving a boring tool or a face plate, and the spindle being mounted to turn and to slide in the direction of its axis.

LOOP SETTER.—J. M. Triplett, 6 North Columbia St., Wenatchee, Washington. This invention relates to moving picture apparatus and provides means for setting the loop of the film without interfering with the operating of the machine. The mechanism is of a simple nature under the immediate control of the operator. It is adapted for use in connection with any standard moving picture machine.

MEASURING AND DELIVERING MACHINE.—H. A. [illegible], Box [illegible], Hammond, Ind. The object of this invention is to provide an improved measuring and delivering machine more especially designed for measuring and delivering loose material, such as coal, grain, ore, and the like, and arranged to insure the free passage of this material from a supply chute to a measuring receptacle.

PROJECTING APPARATUS.—J. H. [illegible], [illegible] Golden Street, Newburgh, N. Y. It is the object of this invention to provide an [illegible] especially designed for use as an advertising medium and arranged to display the images of desired [illegible] on a screen, wall, sidewalk or other surface, together with a revolving image having differently colored sections to form an attractive feature of the display.

SAWING MACHINE.—J. M. [illegible], 921 Poplar Street, Wilmington, Delaware. The invention has for its object to provide an improved sawing machine arranged for quickly and conveniently sawing trees with a view to felling them, and to allow of sawing the felled tree or log into desired lengths of cordwood lumber and other mill material.

AUTOMATIC ANNUNCIATOR.—J. H. [illegible], 13 Golden Street, Newburgh, N. Y. The invention relates to a projecting apparatus for projecting pictures or other subject matter on a screen, walk, sidewalk or other surface. The annunciator is arranged to announce automatically the time and legends representing advertisements or titles to vaudeville acts, or titles for moving pictures, or the like.

Medical Appliances.

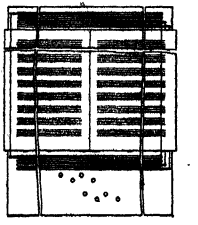
SANITARY MEDICAMENT EJECTOR.—C. E. Brasefield, care of R. C. Collins, Schuylkill Fruit Building, Pottsville, Pa. Mr. Brasefield's invention provides an improvement in the class of devices comprising a rigid tube and an expansible soft rubber bag attached to the tube, for use in applying a medicament to the affected portions of the mucous membrane lining cavities of the body.

Musical Instruments.

MUSIC TURNER.—J. E. Poot, Wetumka, Okla. The invention provides a mechanism for turning the leaves of a piece of music in succession. The mechanism is operated by the foot of the player, and is so arranged that it may be applied to a piano without radical changes in the construction of the instrument.

ROSIN CAKE.—D. C. Lohmann, West Milton, Ohio. The invention relates to a cake of rosin for use in connection with the bows of stringed musical instruments. The rosin cake is formed with soft and hard rosin, the soft rosin serving to hold the hard rosin to the bow. In the soft sections bluing is incorporated, so as to whiten the bow.

MUSIC LEAF TURNER.—A. J. Illig, Box 19, Roseilville, Wis. The present invention provides a leaf-turning mechanism which is manually controlled, but motor-driven, as shown in the accompanying drawing, which is a face view of the apparatus. Rock shafts are provided, with arms extending above and below the music, while wires connecting the arms pass between the leaves of the music. By touching the proper button, any rock shaft may be operated to turn a leaf to the right or to the left, as desired.



MUSIC LEAF TURNER.

Prime Movers and Their Accessories.

PISTON PACKING.—C. N. Bowden, Guantanamo, Cuba. The present invention is intended more particularly for embodiment in hydraulic pistons employing a cup packing, and it is the design of the invention to provide a novel means associated with the cup packing to prevent the latter from being forced between the piston and cylinder wall when either or both become worn.

BOILER AND SUPERHEATER.—J. A. Frey, Silver Spring, Md. An object of the invention is to provide a device by means of which steam which is generated in a boiler may be returned to a superheater disposed within the combustion chamber of the boiler whereby the steam is superheated for use in metallurgical operations, and in which steam at a lower pressure may be taken from the same boiler to run an engine or for any other suitable purpose.

ENGINE.—R. Hunter, 1022½ Sprague Ave., Spokane, Washington. Mr. Hunter has invented an engine of simple design, being an internal combustion engine of the rotary type. The invention provides a governor mechanism adapted for controlling the fuel supply in addition to the usual cam-operated inlet valve.

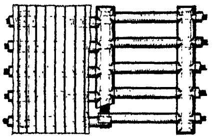
INTERNAL COMBUSTION ENGINE.—F. D. Calkins and A. C. Johnson, Sunnyvale, California. The invention is an improvement in internal combustion engines, and has for its object the provision of a removable liner for the valve chambers of the engine, shown in a series of patents still pending, as means of permitting the linings to be removed, when worn, and replaced by others.

Railways and Their Accessories.

HYDRAULIC WEIGHING SCALE.—E. J. Walters, Groveland, and W. P. Symonds, Arlington, Cal. The invention relates to hydraulic-weighing scales, more particularly of the type used for weighing heavy articles, such as cars of a railway train. In operation, the cars of a train are drawn successively and slowly over the rails on the weighing scale, and a record of the weight of each is made automatically upon a chart.

EXTENSION-PLATFORM FOR CURVED RAILWAY-STATIONS.—J. J. Porth, 72 Main St., Corona, N. Y. To close the gap between a car and a curved station platform and thus avoid accidents from persons falling between the platform and the car, Mr. Porth has provided a series of extension devices, consisting of spring-pressed platform sections, which are normally projected beneath the station platform, to intercept the spaces between the cars and platform.

BRIDGE.—O. Freeny, Carthage, Miss. The invention relates to simple and effective means for protecting and prolonging the life of sills and sleepers of bridges. Sheet-metal shields are provided, which extend longitudinally and transversely above the sleepers and the sills, to protect them from water dripping through the cracks between the transverse flooring strips. The life of the sills and sleepers is thus greatly prolonged, and it is merely necessary, from time to time, to replace the flooring



PROTECTOR FOR BRIDGE SILLS AND SLEEPERS.

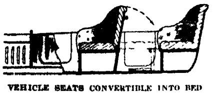
AUTOMATIC TRAIN STOP.—P. N. Mathis, 1639 Pacific Street, Brooklyn, N Y The invention has particular reference to means for preventing an electric car or a locomotive equipped with air-brakes from passing a danger signal, except under direct orders and at low speed. The invention provides mechanism under control of a semaphore or other signal arranged to engage a device carried at the top of the locomotive or car when the signal is kept at the danger point.

VESTIBULE CAR CURTAIN HOLDER —M. J. Roche, 63 Wayne St., Jersey City, N. J. The invention relates to improvements in curtain holders for vestibule cars, and has for its object to provide an improved structure which may be readily attached and detached, and which will automatically become detached when a predetermined strain is brought thereon, whereby the curtain is released without tearing.

FENDING DEVICE.—M. Cohen, 62 Avenue B, New York, N. Y. The invention provides a fending device adapted to be applied to street cars, automobiles, or other vehicles. The device comprises a movable shield adapted to be locked automatically in front of the fender, to shield a person struck by the fender and prevent him from being rolled or thrown to a position to be run over by the car.

Pertaining to Vehicles.

HINGED SEAT FOR VEHICLES.—J. L. Beeson, Milledgeville, Georgia. The object of this invention is to provide the front seat of an automobile or other vehicle with a back which may be let down so as to form, in connection with the rear seat of the vehicle, a bed This would be found particularly useful for camping purposes. The design is such that when the seat back is replaced in its normal position, it will have the appearance of a seat of the ordinary construction



VEHICLE SEATS CONVERTIBLE INTO BED

AUTOMOBILE LOCK —F. O Ulrich, care of John O. Ulrich, Tamaqua, Pa The invention provides a means for locking the steering wheel of an automobile to the bearing post sleeve, so as to prevent unauthorized interference with the wheel during the absence of the owner. It consists of a bolt mounted on the wheel and movable from the bearing sleeve, together with means for holding the bolt in operative or inoperative position.

REAR-END SIGNAL FOR VEHICLES — C. F. Marston, 104 India St., Brooklyn Mr Marston provides a foot-pedal controlling mechanism for a vehicle whereby the driver of the vehicle may actuate signs selectively to indicate his intentions, the sign being placed at the rear of vehicle, but being selected with the foot pedal electrically

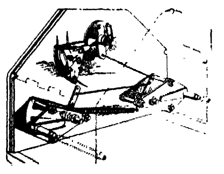
DRAFT EQUALIZER.—A. Lange, care of H. M. Kidder, Fremont, Nebr. The principal object of this invention is to provide means for equalizing the pulling strain exerted by a wide-spread team, to provide a spreader for distributing a team to advantage irrespective of the line of draft and to provide a hitching device whereby unequal pulling strains are equalized.

SPRING WHEEL —G. E. Crawford, Britton, Okla This automobile wheel comprises a hub, side plates carried thereby and formed with elliptical seats, spacing blocks alternating with the seats and formed with screw threads, radially disposed spiral springs with elliptical ends accommodated in the seats and engaging the threads of the spacing blocks and a rim projecting radially into and engaging the outer ends of the springs

TRACTION WHEEL —S H Summerscales, Box 1891, Winnipeg, Manitoba, Canada. In the present invention a traction wheel is provided with a plurality of spuds, for contact with the ground to cause the wheel to "take hold" while the spuds themselves do not sustain the load. The arrangement is such that the spuds contact with the ground in advance of the contact of the wheel tread

CUSPIDOR ATTACHMENT FOR VEHICLES —W. M Carson, Stovall, Miss In carrying out this invention Mr Carson provides the floor of an automobile or other vehicle with an opening which is normally closed by a spring door that is adapted to be retracted and opened by pulling a device connected thereto and easily accessible to the occupants of the vehicle.

LOCKING DEVICE FOR AUTOMOBILE HOODS.—A. E. Marshall, Box 215, Asheville, N. C. The object of this invention is to provide means for locking or unlocking automobile hoods so as to prevent access to the engine or other parts contained therein The locking mechanism serves also as a means for actuating a switch to cut out the sparking circuit Both sides of the hood, as well as both ends, may be simultaneously locked or unlocked



LOCKING DEVICE FOR AUTOMOBILE HOODS.

Designs.

DESIGN FOR WALL PAPER —E J Walenta, Sr., care of Standard Wall Paper Co., Hudson Falls, New York The design for wall paper represents a scene through a wooded lane with hills in the background

DESIGN FOR A HAMMERHEAD —W J Fleischauer and H Richardson, 159 Hayne Avenue, Pontiac, Michigan. The distinguishing feature of this design consists in providing at the side of a hammer head a flat circular boss

DESIGN FOR WALL PAPER —E C Baeck, 233 37th St., Brooklyn, N Y The patent covers an ornamental design for wall paper in which the effect of a woven fabric is produced

DESIGN FOR A GAME BOARD —M J Fitzgerald, Lancaster, Los Angeles County, California The game board bears on its face a picture of an animal, such as a bear with a series of circles symmetrically disposed on the board and numbers printed in the circles

DESIGN FOR A THREE-VALVE SHOWER BATH BODY —F Bockelman 551 W 174th St, New York

DESIGN FOR A TWO VALVE SHOWER-BATH BODY —F Bockelman, 551 W. 174th St, New York

DESIGN FOR WALL PAPER —E. C. Baeck, 233 37th St. Brooklyn, N. Y

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

Wireless Telegraphy and Telephony

SIMPLY EXPLAINED

70 Pages *156 Illustrations* *By ALFRED P MORGAN* *Price $1 00 Postpaid*

The simplest, latest and most comprehensive popular work published on wireless, for the Wireless Operator, Amateur or Professional

THIS is undoubtedly one of the most comprehensive treatises on the subject, and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective, showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

A book the wireless experimenter cannot afford to be without. It enables one to design and construct apparatus. Also valuable to the layman

MUNN & COMPANY, Inc., 361 Broadway, New York City

Forty-five Years of Air-brake Evolution

(Concluded from page 498.)

severe service requirements were for a long time partly offset by closer inspection, better maintenance and more care and skill in the handling of the equipment in service.

Recent Improvements in the Air Brake.

The nature of the mechanism, itself, however, has been rapidly and radically modified.

The brake apparatus, in the first place, has been reconstructed so that the mechanism on each car assists in propagating the application in routine as well as in emergency use, thus insuring the prompt and uniform action of all the brakes and affording a more responsive brake for the train as a whole. In "releasing," uniformity and certainty are attained by automatically restricting the release and recharging of the brakes at the head end of the train. This insures greater certainty of response of the brakes toward the rear end of the train and a more uniform action on the train as a whole and is a large factor in preventing the shocks and strains which cause rough handling and break-in-twos.

To meet down-grade conditions the "empty and load" type of brake has been evolved. Instead of the ordinary brake, designed to control the empty car, and about one-third as efficient with a loaded car, we have for heavy grades the "empty and load" brake providing a braking force on each car substantially in proportion to its weight. The more uniform braking of loaded and empty cars improves level as well as mountain-grade service, since any inequality of braking effort on different vehicles in mixed trains of loads and empties produces rough slack action and damaging shocks.

Increased consumption of compressed air took place through greater loss by leakage for longer trains and larger cars, through greater actual use on the larger cars and in more frequent and heavier brake application. To augment the supply of compressed air, compressors of large capacity and high efficiency have been developed.

While the brake could be made quicker acting and more powerful by propagating the application through the train more rapidly, by raising the cylinder pressure and by shortening the time required in obtaining this high maximum pressure, thus making substantially safer the passenger train with heavy cars, it came to be recognized that full results depended upon transmitting the enhanced and quickened pressure to the rim of the wheel efficiently and without material loss. This brings us to the foundation brake rigging—the brake beam and levers—and the brake shoe. Inefficiency in these parts of the mechanism, as the Lake Shore tests of 1909 graphically demonstrated, made it impossible to reduce the length of emergency stops on heavy passenger trains going sixty miles an hour to less than 1,200 feet with the most powerful and rapid-acting brake then available. The result has been a highly efficient "clasp" type of rigging; two brake shoes to the wheel instead of one greatly improved the performance of the rigging and relieved the brake shoes, trucks and journals of excessive and unbalanced forces to such an extent as to permit the stops already described at well under 1,000 feet.

Routine or "service" stops, as previously pointed out, are second in importance only to emergency stops. The service functions have been improved so that a fully effective automatic or manual emergency application is possible, even at a moment when a "service" application is in progress. In case the brake-pipe reduction is continued below a fixed minimum danger point an emergency application is made automatically. By the use of electro-pneumatic control the application and release of all brakes can be made uniform and simultaneous throughout the train.

The motive of economy as well as that of safety has been assuming more and

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN

more in true position, and the present appreciation by railway officials and manufacturers of this aspect of the braking art promises still further progress in the future.

Making Money Out of Butterflies

(Concluded from page 505.)

kind of food plant shall be at hand; and some few cannot be induced to do their duty under any circumstances, though coaxed in every way possible. But when a female butterfly does lay she makes all efforts on the part of her keeper seem worth while. Often she produces anywhere from one to three hundred eggs. It is hardly profitable to maintain in captivity the commoner species; dealers can use but few of them as a rule. However, as Miss McGlashan soon discovered, the beginner had better secure all the varieties possible. The experience is valuable. Males necessarily must be admitted for breeding purposes. After mating, however, the sexes should at once be segregated.

The feeding of the captives is no problem. They thrive equally well on dried apple soaked in honey or sugared water. A bit of this may be fed daily.

Members of the rarer species bring big prices. There are some butterflies in the Sierra Nevada Mountains worth five dollars each. Incidentally, it might be worth while for the amateur butterfly farmer to know that these mountains also produce a beetle that dealers are anxious to snatch up at that same substantial price of $5 a head. This beetle makes an excellent side line.

But $5 apiece pales into insignificance compared with the almost fabulous sums that certain elect lepidoptera command in Europe. Some of the butterfly farmers there have reared specimens selling for $5,000. An Englishman named Head, who has been in the business for nearly thirty years, has disposed of hundreds of thousands of "flies," and holds the doubly envious position of having made a *fortune* from his enterprise, and of having become a world authority on the rearing of the insects.

Miss McGlashan does not market her "crop" on the basis of individual value of specimens. She has a contract, whereby she receives a uniform price for all, whether rare or common. The reservation, however, has been made by the dealer that the commoner varieties shall be limited to one hundred each.

To catch moths, sugared cloths must be stretched while it is still daylight, on the trunks of trees. If one throws a light upon these cloths after darkness falls, many moths will be found gathered feeding. A carbide lamp is the best for the purpose. It will not blow out in any wind. The price is about two dollars. The light-dazed moths are easily swept into wide-mouthed bottles.

Larvæ or caterpillars, which should be captured whenever found, are also quite easily taken at night. Where the leaves of bushes or trees appear as if they have been fed upon, trays, paper, or sheets should be set upon the ground directly beneath. At 9 o'clock or even later, the raid may be made upon the larvæ. The bushes and branches must be beaten vigorously with a stout rod or pole to break the hold of the feeding larvæ. Dozens, even hundreds of caterpillars, have been taken by Miss McGlashan in this manner in a single evening. Larvæ should be taken even more eagerly than the fully developed female butterflies. The intermediate stages of egg-laying and hatching can thus be dispensed with. The taking of both moths and larvæ can, of course, be combined the same evening. It is advisable to do this work alone as moths are easily frightened away by noise.

All the work of butterfly breeding centers in the care of the caterpillars. It is of vital importance, first of all, that the little creatures have their own sort of food. Usually this may be known, of course, by a knowledge of the sort of bush the captives were found feeding upon. However, where the farmer has hatched his caterpillars from eggs, a problem pre-

sents itself. But the right sort of food plant may be discovered by making various experiments, half a dozen different varieties of leaves being introduced each day until it is observed that the larvæ begin to cluster upon some one of these. There is no danger of immediate starvation, for they will subsist for a little time upon the shells from which they have been hatched.

Miss McGlashan found that test tubes are the best place in which to keep the eggs. As they must be examined every day to see whether or not they have hatched, the importance of having transparent receptacles that may also be easily handled, is obvious. The eggs of some species of butterflies will hatch within a few days, others not until the following Spring. Larvæ and eggs should be put in cold storage for the Winter. The reason for this is that the food plants not being available, the caterpillars would starve. Thus, the eggs will not hatch till Spring, and the caterpillars will hibernate until warmer days arrive.

At intervals larvæ molt. This process goes on half a dozen times during the crawling stage of their existence. When they begin to spin cocoons, the nursing period for the farmer is over. His last step is to remove the cocoons to a barrel or box securely covered with gauze.

Miss McGlashan thus gives directions for taking care of young caterpillars:

"A few days after they have hatched, remove your brood of worms to a jelly glass having a tight-fitting tin cover. They may remain here until they become a quarter of an inch in length. Then place them in large-mouthed bottles with tight-fitting covers. They require very little air. Large bottles or fruit jars make fine breeding cages for broods of caterpillars. A candy jar is ideal, because you can watch the development of the larvæ through the thin, transparent glass. If you have hundreds of a kind, get a tight barrel, loosen the top hoop, place a covering of cloth or gauze over the open head of the barrel and fasten it down closely by means of the hoop, and you have a first-class breeding cage. Three inches of dirt and leaf mold should be placed in the bottom of each bottle or barrel used for larvæ, because they love to hide in this during the daytime, and many species bury themselves before they pupate. Put in fresh leaves of the food plant daily, take out the old food and keep your breeding cages clean. Of course, you may build elaborate cages of wire gauze, but the simple ones are just as good."

The Improvement of the Irish Potato has been the subject of much recent investigation on the part of the United States Department of Agriculture. An initial step has been the exploration of that portion of South America of which the potato is supposed to be a native. Convincing proof has been obtained that this plant was indigenous to the high Andes region of both Peru and Bolivia, where it has been under cultivation for 2,000 years. Experts of the Department have collected more than 250 sorts of cultivated and wild potatoes, which will be used in the development of more vigorous races especially adapted to the diverse areas over which the potato is cultivated in the United States. The Department is also investigating new methods of utilizing potatoes analogous to those that have been so successful in Germany.

Salton Sea continues to dwindle in size and increase in salinity through evaporation. The last (seventh) annual analysis of its water, made by A. E. Vinson, showed that the total solids in the water had increased in a year from 846.55 parts to 1,002.56 parts per 100,000, an increase of 18.4 per cent for the period. The water may now be considered as 1 per cent brine.

Mr. J. I. Craig, late director of the meteorological service of Egypt, has been transferred to other duties in the Survey Department (of which the meteorological service is a branch), and is succeeded by Mr. H. E. Hurst.

NEW BOOKS, ETC.

Animal Flight. A Record of Observation. By E. H. Hankin, M.A., Sc.D., Associate Fellow of the Aeronautical Society of Great Britain. London: Iliffe & Sons, Ltd. 8vo.; 413 pp.; illustrated. Price, 12s. 6d. net.

The author once asked Lord Kelvin if he could explain the baffling phenomena of soaring flight, and received the answer, "That which puzzled Solomon puzzles me also." "Animal Flight" is largely devoted to bird soaring, although other modes of bird flight are included, and there are chapters dealing with bats, flying fishes, and dragon-flies. The volume is unique in that the writer has no theories of his own to proffer. He simply presents atmospheric conditions, time and space measurements, and actual accomplishments, leaving the field of deduction to those who may follow him. He has had splendid opportunities for intimate observation, and has not failed to make the most of them. There are instances of heavy birds soaring in calm, tropical air, and he differentiates between true soaring flight such as this and the more usually seen mode in which our birds of the temperate zone skillfully seek and utilize air currents. Although the author avoids speculation, it is clear that he believes the possibility of soaring flight to be traceable to a certain condition of the air, a static energy dependent in its turn upon sunlight. Hence we find him continually applying to the air the terms "soarable" and "unsoarable." Perhaps the more immediate value of the work lies in its studies of wing positions, camber, etc., in the various modes of flight.

Noted Murder Mysteries. By Philip Curtin. London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. 8vo.; 301 pp. Price, 7s. 6d. net.

Without straining toward sensationalism, allowing the actual circumstance and situation to exert their own power, Mr. Curtin narrates nine of the world's strangest cases. Whether Marie Lafarge was martyr or murderess will probably never be known, but in its day her case rocked emotional France, and as retold by the present writer, still has the power to arouse in the reader strong conflicting emotions. But a very low wall divides the commonplace from the tragic. Certain stimuli are raised above the threshold of consciousness. The wall is leaped; and immediately some humdrum life appears before the world in all the colors of romance, with tonal values ranging from humor to tragedy. Strange flashlights play upon the inscrutable depths of human nature, and the observer is held motionless, fascinated. For those who care to indulge in this form of intellectual dissipation, "Noted Murder Mysteries" will furnish a ready means.

Sun Lore of All Ages. A Collection of Myths and Legends Concerning the Sun and Its Worship. By William Tyler Olcott, A.M. New York: G. P. Putnam's Sons, 1914. 8vo.; 346 pp.

Those who are familiar with the author's companion volume, "Star Lore of All Ages," need no assurance that in beauty of format and wealth of illustration this later work is worthy of a place beside the former. From earliest times, and among the most primitive peoples, the heavenly bodies have made an intense appeal to religious, superstitious, and scientific instincts. Imperious and dominating among these celestial mysteries rides the sun, and the wealth of the mythology clustering about it is well represented and set forth in the twelve chapters of this work. In them is included the solar creation myths of the North American Indians, the legends of India, Persia, and Greece. The solar festivals of many lands are described, and their folk lore is frequently presented in the language of their own literatures. Thirty full page plates embellish the text, many of them reproductions of beautiful sculptures and paintings that are not so well known as to carry with them that familiarity which, while it can never breed contempt in the artistic mind, yet takes off the finest edge of enthusiasm.

Terry's Japanese Empire. Including Korea and Formosa. With Chapters on Manchuria, the Trans-Siberian Railway, and the Chief Ocean Routes to Japan. A Guide Book for Travelers. By T. Philip Terry, F.R.G.S. New York: Houghton, Mifflin Company. 12mo.; 1150 pp.; 8 specially-drawn maps, and 21 plans. 1914 Edition. Price, $5.

Aided by the use of thin but good paper, the author and publishers have packed a really astonishing amount of information into a volume that just comfortably fits the hand. The result is a guidebook dealing substantially with a great diversity of things. The "three R's" of the ordinary guidebook—routes, rates, and recreations—are supplemented by admirable little essays on art, architecture, language, and religion. The main portion of the book maps out seven routes which, together, include all the points and localities that offer special appeal to the tourist. The writer knows his business, as he knows his Japan, and his laborious and conscientious work should be eagerly welcomed by all who contemplate travel through or residence in this most interesting part of the world. Terry's "Mexico" is the standard guide to that much troubled (and troublesome) country, and is the only case where a Baedeker has been successfully supplanted. We have no reason for believing that Mr. Terry will be less successful in his newest venture.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short* and the facts *authentic* the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Valuable Data for the Aeroplane Builder

THERE can be no doubt that the excellent progress which is being made in Great Britain in practical aeronautics is in great measure due to the experimental work which has been done at the National Physical Laboratory for the Advisory Committee for Aeronautics. The extent and detail of the work of the committee may be judged from its fourth annual report, which contains more than four hundred pages, and embodies no less than twenty-eight separate reports. Limitations of space prevent any elaborate review of this work, and we shall merely attempt, here, to sum up the more important findings.

From the report on experiments with models of aeroplane wings we learn that good results will be secured by placing the maximum ordinate of the wing section farther from the front edge than is the present practice. Furthermore, so far as the aerodynamics of the wings are concerned, there is nothing to be gained by thickening the leading edge, although there is no particular disadvantage if the edge is moderately thickened. Of considerable constructional advantage is the fact that a distinct increase may be made in the thickness of the after portion of the wing, without incurring any aerodynamical disadvantage. The value of this fact is that transverse spars of deeper section than are commonly used may be inserted toward the trailing edge of the wing. On the question as to how far results obtained with models may be applied to full-size wings, we learn that the lift-drift ratios of models should be increased from 15 to 20 per cent to make them reliably applicable to full-size wings.

A question which has attracted much attention of late years is that of the value of reflexing the trailing edge of the wings, and it has been established that to restrict or entirely prevent the movement of the center of pressure, when there is a change in the angle of incidence, it is necessary to reverse the curvature in the after portion of the wings. The laboratory tests have shown that absolutely to prevent the movement of the center of pressure in this way, about 12 per cent of the maximum lift-drift ratio must be sacrificed, and of the maximum lift coefficient about 25 per cent.

The report on the distribution of pressure over the surface of the wings brings out the fact that the tips of the wings have a very low aerodynamic efficiency. Good results, according to the report, should follow a careful investigation into the effect of variations of camber, angle of incidence, and plan form in that portion of the wings at and near the tips.

The report dealing with wind forces and moments shows that great accuracy is necessary in giving the struts symmetrical form. If they are not symmetrical, highly unsymmetrical and erratic cross-wind forces will be produced by the struts when the aeroplane yaws from its path. If the struts have a large ratio of fineness, irregularities of construction will have a small effect on the drift and the transverse wind forces. Should the ratio be less than 2½ to 1, the drift will be extremely high, and the transverse wind force will be erratic in its magnitude.

The tests on model aeroplane bodies show that good results are to be expected from giving careful attention to the design of the body. To many aeroplane builders it will be a surprise to learn that, in place of the symmetrical torpedo body form, better results are to be expected if a single boom is extended from the cockpit to the tail planes and elevators.

Tests on a model tail plane and elevator planes prove that the maximum control is reached when the elevators are turned to an angle of 30 degrees, above or below the horizontal; furthermore, the elevating or depressing moments are about proportional to the angle of depression or elevation, until the above-mentioned limiting angle of 30 degrees plus or minus is reached.

Of widespread interest will be the results obtained in the investigations of the gyroscopic action of the engine and propeller. If an aeroplane driven by a 100 horse-power Gnôme engine coupled to a 9-foot 6-inch, 2-bladed, 30-pound propeller, is caused to make a complete turn in 20 seconds, the total gyroscopic couple is found to amount to 324 foot-pounds; and a sudden manipulation of the elevator to an extent just sufficient to raise the pilot from his seat, was found to be 330 foot-pounds. According to the report, these couples are not of serious amount and they can readily be met by the ordinary controls. They act upon the aeroplane in much the same way as a gust of wind; but there is the advantage that both the magnitude and the direction of the gyroscopic couples are known and the pilot is prepared for them.

The report on model propellers endorses the present method of design in determining their section, etc. Under the present method each section of the blade is considered as a small aerofoil, and is designed accordingly. The report shows that the method is not strictly correct, and that the calculated thrust, torque, and efficiency are slightly less than that obtained by the accepted method. The laboratory experiments proved that a certain type of propeller should have had a maximum efficiency when the angle of attack was 4 degrees. This efficiency, however, was not reached until the angle had been raised to 9 degrees.

"Boats for All" a Failure

GRADUALLY, but very surely, it is coming to be realized that the only way to safeguard the lives of passengers at sea is so to build the ship which carries them that it shall act, in case of necessity, as its own lifeboat—in other words, to make the construction such that no accident could send it to the bottom with the suddenness which marked the sinking of the "Empress of Ireland."

The principle of safeguarding the passengers by providing boats for all is faulty, for the reason that it assumes that certain conditions of wind, weather, and time, all of which must be present if the boats are to be launched, will exist when the emergency calls for their immediate use. In the case of the "Titanic," these conditions fortunately happened to exist. There was no wind, the sea was calm, and the two hours and twenty minutes from the collision to the sinking of the ship provided sufficient time to utilize practically all the boats that the ship carried. In the case of the "Empress of Ireland," however, although there was no wind and the sea was calm, and although there were more than sufficient boats to carry everyone on board, the ship listed so heavily, and went under so quickly, that only a very few of the boats were got into the water.

It is gratifying to note that the *Engineer* of London, an organ of very high authority in maritime matters, has come to our point of view in this most serious question. In its issue of June 5th, in discussing the recent disaster, it says: "One cannot help reflecting that here, again, as in the case of the 'Volturno,' the principle of 'boats for all' has signally failed. The 'Empress' could have carried every soul on board in her boats, but she had no chance to use them." On another important phase of this question, the *Engineer* is in agreement with us; for farther on in the same article it says: "The 'Empress of Ireland' was built by Fairfields, in 1906, on lines that were considered the best before the loss of the 'Titanic.' She had an extensive double bottom, and was well divided, *but she had no inner skin.* (The italics are ours.) Whether an inner skin would have saved her, under the circumstances of the collision, is a question which the evidence of the divers may help to answer. . . . But there seems to have been no question of cutting her in two. The effect, from the meager evidence we have, seems rather to indicate that the plates were ripped off by the bow of the 'Storstad,' as we rip the lid off a box with a screwdriver. If the divers can substantiate this view, a very strong case for the double inner skin will be presented. For it is probable that while many ribs would, of necessity, have been badly distorted, yet the inner hull might have held, at least for a time."

We attach the more importance to this admission on the part of our contemporary, for the reason that its attitude at the time of the "Titanic" disaster was rather unfavorable than otherwise to inner skin construction. The only valid objection against the inner skin, particularly if it consists of the inner walls of coal bunkers, is that the inflow of water is confined to one side of the vessel, and that heavy heeling, which might become disastrous, would be occasioned. The answer to this is that, if provision were made for flooding the corresponding compartments on the opposite side of the ship, it would be possible to maintain her equilibrium by quickly admitting sufficient water for the purpose. Battleships are built on this principle, and there is no constructional difficulty which would prevent its being applied effectively to large passenger-carrying ships.

There is yet ample time for the consideration of amendments to the convention drawn up in London, last Winter, by the International Conference on Safety at Sea. The insertion of a clause, rendering the use of some form of inner skin on the large passenger-carrying ships, not, as it is at present, optional, but strictly obligatory, would round out and complete the otherwise excellent work of that congress.

As these words are being written, there comes the startling information that, for the third time in less than a month, a transatlantic liner has been run into by another ship. A little over two weeks after the loss of the "Empress of Ireland," the "New York" was rammed by the "Pretoria"; and a few days later, the "Kaiser Wilhelm II," while crossing the English Channel, was struck squarely amidships by another vessel. Both ships, fortunately, are subdivided far more effectively than the avearge ocean liner—the "New York" having closely-spaced transverse bulkheads, carried to an unusual height above water, and the "Kaiser Wilhelm II" carrying a continuous inner skin throughout the engine and boiler-room spaces. The "Kaiser" reports that water gained admission only to one compartment, probably a side bunker of small capacity. Had she been built as are 95 per cent of the passenger ships, the water would have had free access to the whole width of the ship.

Evolution and Physical Law

THE division of human knowledge into separate fields of science is more or less arbitrary, and chiefly due to certain peculiarities of our senses. It is therefore to be expected that the most fundamental principles of science shall be of universal application, and shall be found to hold, in some form or other, in widely separated branches of science.

In the biological sciences, one of the most fundamental principles is that of evolution by the survival of the fittest. What is there corresponding to this in the purely physical sciences?

Evolution, as understood by the biologist, is an essentially one-directional process in time, an advance or development, to use expressions which are illustrative rather than precise.

Now the physicist is acquainted with two kinds of processes. There are purely mechanical processes. A peculiar property of these is that in them time does not enter in a one-directional way. It can be shown that if all the motions of a purely mechanical system were instantly reversed, it would exactly retrace its history. There is thus nothing unique in the actual history of a purely mechanical system.

But in all other systems, and that is to say all *real* systems, which are not purely mechanical, there is dissipation of energy through degradation of other forms into heat, and through passage of heat from higher to lower temperatures. In such a system the one-directional character of time is again apparent and finds its exact expression in the second law of thermodynamics. This law can be stated in various forms. For purposes of a popular exposition, it is perhaps best presented in some such terms as these: Heat cannot, of itself and spontaneously, i. e., without compensating change of some kind, pass from a colder to a hotter body.

The more technical statement of the law is to the effect that the *entropy* of an isolated system can only increase, not decrease, with time. Or in other words, the entropy of such a system tends toward a maximum.

Now there are certain systems, as for example a system comprising several substances undergoing chemical reaction, the history of which can be forecast by application of the entropy principle alone. The system will ultimately reach a state of equilibrium in which the entropy will be a maximum. The entropy principle in such a case is *the law of evolution.*

In the case of the highly complex system presented to us by the living world, this statement alone, though it may be correct, fails to carry all the information which the biologist seeks. Still, here also, we know, evolution is a one-directional process, and it may reasonably be expected that the law of evolution takes a form similar to that of the second law of thermodynamics. Some function of the state of the system tends toward a maximum. But what is that function? This is a problem which remains to be solved.

A Wireless Receiving Installation now in use at the Duomo, in Florence, is interesting for the fact that the entire outfit, including the antennæ, is inside the cathedral. Messages received from points as far distant as Paris, Madrid, and Toulon indicate that the apparatus is hardly less efficient than if installed out of doors.

[illegible]

[illegible]

[illegible] and Passenger Cars.—It is [illegible] Pennsylvania Railroad Company that passenger [illegible] a useful life of 20 years, at [illegible] value as scrap will be only [illegible]. An allowance [illegible] and renewal is made for [illegible] for locomotives and passenger [illegible] of 4 per cent. is made [illegible] and renewal. This seems to us to be a [illegible]

[illegible] Lifeboats.—After the burning of the [illegible] steamship "Columbian," one of the [illegible] for no less than two weeks in the path of [illegible] steamers, but although the wretched seamen [illegible] they could not attract their attention by signals. Of the 15 men in the boat, 11 died before [illegible]. Had the lifeboat carried a submarine bell, it could have signaled Atlantic steamers which were suitably equipped, even at a distance of several miles. The suggestion is well worth careful consideration.

Fewer Rail Failures in New York State.—Thanks to better methods and better materials, there has been a great improvement in the quality of rails laid throughout this State during the past three years. Thus, in the three months, January, February and March, there were in 1912, 3,6[illegible] rail failures, the large number being due mainly to the severe Winter. In the same three months in 1913, when the weather was mild, the rail failures were only 1,1[illegible]. But for the same three months in 1914 when the weather was nearly as bad as in 1912, there were only 1,[illegible] rail failures, a most encouraging showing.

Another Fifteen-Cubic-Yard Dredge for the Panama Canal.—In our issue of May 9th, we illustrated the "Gamboa," the largest dipper-dredge ever built, which is now doing good work on the Cucaracha slide in the Culebra Cut, Panama Canal. This dredge, built by the Bucyrus Company, South Milwaukee, Wisconsin, especially for the Panama Canal, has a dipper of 15 cubic yards capacity. The second of the dredges, the "Paraiso," built by the same company and a duplicate of the "Gamboa," left New York Harbor in tow on April 26th, and will very soon be at work with the sister dredge, cleaning up what remains of the great slide.

Panama Canal Built Within Estimates of Unit Costs.—The engineers of the Panama Canal must be congratulated on the fact that they have built the canal within the original estimates of unit costs—something very rare in work of this magnitude. The estimate of cost of dry excavation for the Culebra cut was 80 cents per cubic yard, and it was actually built at a cost of 76.18 cents. The estimate of $8 per cubic yard for concrete in the locks was also above the actual cost, which was $7.14 per yard at Gatun, $5.89 at Pedro Miguel, and $5.37 at the Miraflores locks. Dredging in the harbors and entrances was estimated at 25 cents per cubic yard. The actual cost was 23.25 to 25.52 cents per cubic yard.

Trial Trip of the Largest Freight Locomotive.—The "Matt H. Shay," the large triple Mallet locomotive, built by the Baldwin Locomotive Works for the Erie Railroad, and recently illustrated in this journal, has made a trial trip over the Baltimore & Ohio Railroad from Baltimore to Philadelphia. The train load consisted of 53 coal cars carrying 4,012 tons of coal. The total weight of the whole train, including the locomotive, must have been about 6,500 tons. The train left Baltimore at 6:30 in the morning and reached Philadelphia at 4:30 in the afternoon, taking 10 hours and 20 minutes for the 99-mile trip. The engine weighs 423½ tons in working order, and its drawbar pull, working compound, is 80 American tons.

Successful Automatic Train Stop.—Six months of operation of the Miller automatic train stop on 24 miles of the Chicago & Eastern Illinois Railroad is reported. The system has been in place on one of two tracks on the section of the road in question, and 80 freight and passenger locomotives have been equipped with the necessary apparatus. On other sections of the road, some 30 miles have been equipped, and will be put in operation. The system includes a vertically-moving bar on the engine and a ramp on the roadway. Operation [illegible] conditions of sleet and snow, [illegible] "safety factor," is [illegible]

Science

[illegible] for Science.—A great hospital and medical school for St. Louis University is provided for in the will of James Campbell, filed in the Probate Court at St. Louis on June [illegible] last. The entire estate, valued at between $[illegible] and $40,000,000, with the exception of $1,000,000, eventually goes to the university "for a hospital for the care of sick and injured persons," and the "promotion of the sciences of medicine and surgery."

Extensive Scientific Investigations in Porto Rico, covering a period of four years, have been undertaken by the New York Academy of Sciences, with the financial co-operation of the American Museum of Natural History, the New York Botanical Garden, Columbia University, New York University, and the government of Porto Rico, and under the direction of a committee consisting of Profs. N. L. Britton, James F. Kemp, Franz Boas, C. L. Poor, and H. E. Crampton. The programme includes studies in anthropology, archeology, botany, zoology, geology, oceanography, etc. The reforestation of certain parts of the island is one of the practical problems to be investigated.

Relief Model of Hawaiian Craters.—A remarkable relief model of the craters of Kilauea, Kilauea-Iki and Keanakakoi, in Hawaii, has been made by George Carroll Curtis, of Boston, for the Harvard University Museum, to which it is a gift from Robert Sayles, curator of geology. Mr. Curtis spent three months in making a photographic survey of the region, establishing a network of flag stations and photographing from all of them. He states that this was "probably the most comprehensive survey of its kind yet made for the reproduction of a land-form type." It is expected that a copy of the model will be exhibited in the Hawaiian building of the Panama-Pacific Exposition.

The Windiest Region of the World of which we have any knowledge appears to be the coast of Wilkes Land, where Dr. Mawson's expedition recently spent two years. In his presidential address before the Royal Society of New South Wales, Mr. R. H. Cambage recently stated that Mawson's records at Adélie Land for 1912 showed an average wind velocity throughout the year of about 48 miles an hour, while velocities of 100 miles an hour were common. This surpasses even the records made on high mountains in other parts of the world, e. g., on Mount Washington, N. H., where the former meteorological station showed an average velocity of only 41 miles an hour during the Winter, and much lower velocities in Summer.

A Barometer Graduated in C. G. S. Units.—A well-known firm of instrument-makers in London has put on the market a new form of aneroid barometer, which was designed under the direction of Dr. W. N. Shaw, the head of the British Meteorological Office. The new instrument has several concentric scales. The outer is figured in centibars and subdivided to millibars. This scale can be adjusted according to the altitude of the place of observation, and then gives sea-level readings, such as are used for many purposes in meteorology. Along this scale is engraved the new nomenclature, "very low," "low," "normal," "high," "very high," in place of the time-honored but misleading terms "fair," "change," "rain," etc., which appear on nearly all existing barometers except those constructed strictly for scientific use. The frequency of occurrence of various readings, in days per year, at three representative English observatories, is also engraved on the scale, so that the observer can tell just how a reading compares with average conditions. The next inner dial is also in the centibar scale, but is fixed, and therefore gives the actual value of the pressure, unreduced for altitude. Lastly, two more scales give readings in inches and millimeters.

Ammonia and Nitrate in Rain.—Plant physiologists once believed with Liebig that a considerable part of the nitrogen utilized in the nutrition of plants was obtained from rain. Although this view has been abandoned, the amount of ammonia and nitrate in rain water has remained a favorite subject of investigation, and a great number of analyses have been made in various parts of the world. These have been brought together by Dr. N. H. J. Miller, in an article on "The Composition of Rain Water Collected in the Hebrides and in Iceland," published in the Journal of the Scottish Meteorological Society. The principal object of Dr. Miller's inquiry is to ascertain from what source these nitrogenous components of rain are derived. The old idea of Boussingault that atmospheric ammonia is derived from the sea, and the later one of Schloesing that tropical seas yield ammonia to the air, appear to be refuted by the fact that analyses of rain collected near the sea in tropical countries show less ammonia than is found at Rothamsted. Samples of rain collected systematically from various stations in the Hebrides and in Iceland, remote from sources of atmospheric pollution, contain ammonia and nitrate, but in very small amounts. In fact, the rain at the Butt of Lewis, in the Hebrides, contains less ammonia than at any other place in the world at which samples have been taken, being even less than was found in the Antarctic by the [illegible] expedition.

Automobile

Eliminating Glare from Headlights.—Still another solution of the troublesome problem of eliminating the confusing and dangerous glare from high power motor car headlights has been proposed, this time by the National Physical Laboratory of England. This body has been studying the question at the request of the London authorities. It proposes, briefly, to cut off the light beams coming from the upper right hand corners of the lamps, and in this way to provide a zone of darkness, if such it may be termed, so that an approaching driver will not be blinded. The right hand corner is chosen for the reason that in England the rule of the road is to the left. The arrangement provides ample light, yet appears to solve the glare problem.

A New Type of Differential Mechanism.—The motor car differential, that more or less weird mechanism which few but engineers really understand, always has constituted a knotty problem. By way of assuring that both rear wheels will rotate at the same speed on a straight road, regardless of traction obtainable at each, an inventor has perfected a new mechanism which differs from others principally in that it incorporates a plate clutch. The two plates of the clutch are connected one to either side of the divided rear axle and are held together by a spring. Thus when the car is traversing a straight road, the two halves of the axle must rotate at the same speed, for they are virtually locked together. But when the vehicle rounds a curve the clutch slips, permitting one of the rear wheels to rotate faster than the other. Obviously the mechanism has faults, for there must be considerable wear in the clutch; but the device indicates that attention is being given this problem.

Comprehensive Fuel Economy Test.—Tests of the fuel economy of motor cars by factories have not always been as convincing to the lay public as might be desirable to those who make the tests. Recently, however, the Franklin was subjected to a combination test and demonstration that cannot fail to prove convincing. Ninety-four dealers in Franklin cars, located in as many American cities, each fitted one of his six-cylinder cars with a tank containing one gallon of gasoline, and under the observation of disinterested persons drove the car until the fuel gave out. The tanks were certified, as was the quantity of fuel they contained. The average consumption of the 94 cars figured out at 32.8 miles per gallon of fuel. The greatest mileage obtained was made by a dealer in Milwaukee, Wis., who drove his car the almost incredible distance of 51.2 miles on one gallon of gasoline; the weather was fair. A dealer in Georgetown, Texas, drove 17.2 miles in a rainstorm.

Steam Car with Complete Condensation.—The difficulty of obtaining really efficient condensation placed what appeared to be an effectual bar before the steam automobile some years ago; mileage was limited because of the limited amount of water that could be carried. Now, however, this difficulty would seem to have been overcome in a car that has just made its appearance in Waltham, Mass. A double-acting, single-expansion steam engine with two cylinders measuring 4 x 6 inches is used. A fire tube boiler is used, with 158 feet of heating surface, and heat is supplied by a kerosene burner; it is said the car will run 10 miles to the gallon of kerosene. The condenser is the interesting part of the car. It is an ordinary honeycomb radiator, such as is used on gasoline automobiles for the cooling system. The exhausted steam is carried directly to the top of the radiator, whence the condensed water passes back through a Venturi mixing chamber to the water tank; the temperature of the water in the radiator never exceeds about 100 deg. Fahr. The car is capable of a speed of 75 miles an hour and will accelerate to 60 miles an hour on 800 pounds steam pressure, which is normal, in 15 seconds, from a standing start.

German Tests of Military Trucks.—The German army is engaged upon a series of tests upon military power wagons, and these comprise three different trials upon the road in the shape of endurance tests. The Berlin automobile corps is divided into two columns, and the first of these proceeds toward the Riesengebirge in order to make a circuit through these mountains, which will be a rather severe trial, while the second column goes to the southwest to carry out its programme in Bavaria. On the other hand, the automobile corps of Saxony are engaged in making an endurance test toward Switzerland and the Erzgebirge. Thus all the German heavy trucks are upon the road. Another endurance test of an interesting character was organized by the German Automobile Club for various automobiles as well as motor tricycles and the like, and as it took place in the Harz Mountains the cars had a very hard time, owing to a snowfall of two or three feet on the roads near Clausthal. Here the roads were also cut up by country sledges, so that this occasioned much difficulty. Cycle cars used chains and ropes wrapped around the tires so as to avoid slipping. However, the selected route proved to be too hard, so that an easier circuit had to be chosen. Most of the vehicles showed a good performance on this occasion.

How Inventors Propose to Save Men From Sunken Submarines

Detachable Buoyant Conning Towers and Their Uses

By Major H. Bannerman Phillips

THERE have been seventeen serious submarine accidents in the last ten years, of which eleven occurred to British vessels. The total number of lives lost in submarines up to the present date amounts to 211

With regard to the question of having special "lifting ships" in readiness to meet accidents, it has been pointed out by naval officers, first, that British submarines are stationed all round the coast—at such places as wide apart as Plymouth, Portsmouth, Harwich, Dundee, and Lamlash, as well as at places abroad, like Gibraltar, Malta, and Hong Kong, and that those attached to home ports go to considerable distances and dive in various places, so that it would be impracticable to have lifting-vessels standing by in all cases. Secondly, they say that in scarcely any known instance would a lifting ship have been of assistance in saving life, if it had been available, and that in all cases of accident where life has been preserved, it has been due to the efforts of the crew themselves without any outside assistance

On the other hand, it has been said that officers and men of the submarine service have not hitherto attached much importance to life-saving appliances as applied to the particular vessels for which they are responsible. They have said that the air-lock and helmet might enable men to escape if circumstances were propitious, but that these same circumstances are not likely to be propitious in the case of accidents On the contrary, they know full well that, if anything serious happens to a boat, the crew are almost certain to lose their lives, and they accept the risks as part of "the day's work"

There is no doubt that the accidents due to what may be called true submarine risks, that is, mishaps which are not caused by external interference, such as collisions, and are due to causes and circumstances inherent to the system, are steadily on the decrease, and this satisfactory result must be ascribed to the constant improvements in construction and equipment For instance, in the "A" class of submarine in the British service (13 boats) 25 lives have been lost by collision, and 32 by foundering and explosions. In the "B" class (11 boats) 15 lives have been lost by collision—none through other causes In the "C" class (38 boats) 13 lives have been lost by collision and one by explosion. In the "D" class no lives have been lost so far; in the "E" class there has been one accident from explosion, which was responsible for the loss of three lives

Whatever the cause of the mishap to the "A-7," there is apparently no known reason to suppose that the conning-tower was damaged. It doubtless remained clear of the sand and mud in which a portion of the vessel was imbedded, and under such circumstances, although the airlocks and helmets may not have been of any use, owing to the depth, if the conning-tower had been detachable as a whole apparatus, water-tight and provided with air-storage, which would rise on being set free from the hull, there would have been some chance of rescuing the crew, provided they were not killed by the same cause which prevented the rising of the submarine itself. One such apparatus has been designed and patented by Mr. E. J. Castle, a retired draughtsman from His Majesty's service, and another by Mr. G. Fitzhardinge Rose of London.

Mr. Castle's idea is, to use his own words, referring to the illustration of the invention, as follows:

"To fit two towers, 5 feet in diameter, and about 5 feet 6 inches deep, constructed of steel, well strengthened inside with brackets and steel angles, and placed on the water-tight bulkheads By this method, in the event of any one compartment getting waterlogged by escaping into an unflooded one, the crew can release themselves from the vessel by opening the escape scuttles on either side of the bulkhead in submarine and towers, and closing both when inside (making the vessel intact) and detaching them by means of clips. In the case of the "Lutine" (French submarine) where all the crew were lost, some escaped from a flooded to an unflooded compartment, and lived for an hour, but there was no detachable tower or other device by which they could get out. By my method escape is afforded from three compartments for about 8 to 10 men in each. A small hydraulic is provided for the purpose of exerting an upward pressure if required.

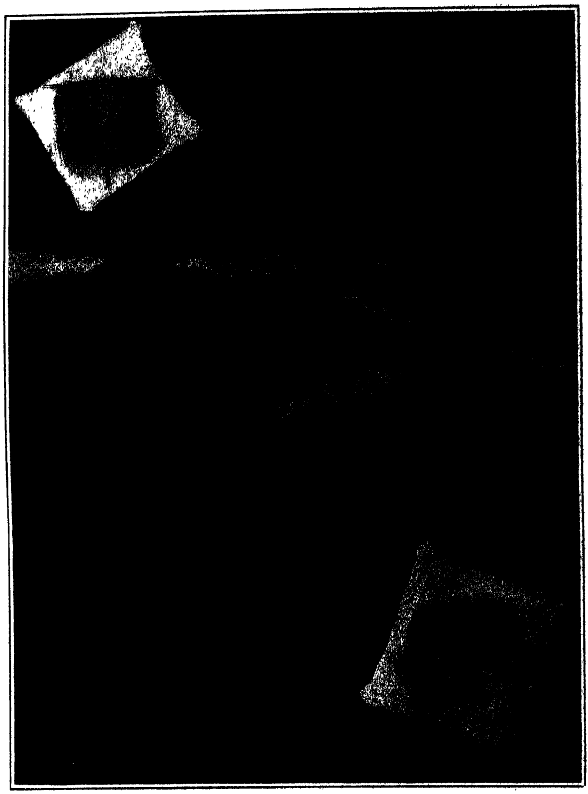
"On the manhole cover in each tower is a signal apparatus fitted with a cork buoy, which, on being released from inside by turning back the screw, rises to the surface, taking with it a fine flexible steel wire line; communication can be made to those inside the towers and at the surface, and will show the position of towers. The towers [illegible] the deck, but they can be fitted at [illegible] resistance if required.

"A flexible wire is stowed in a [illegible] resting upon it, the wire passing [illegible] have a vertical pull in the event of [illegible] The alarm is located below the cover [illegible] purpose of keeping the towers stable [illegible]

"Although the fitting of chambers [illegible] few have been patented, this plan is [illegible] if tried would be found to be practical [illegible] purposes, and would not weaken the [illegible] time giving good chances for the crew [illegible] at great depth. There would be a [illegible] ent [illegible] age in case of collision, but still the vessel would continue to be [illegible]."

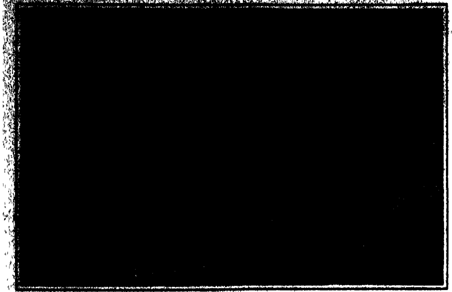
Mr. Rose's invention, pictured on the cover of this issue, includes a submarine lifeboat and buoy. The lifeboat consists of a cylindrical chamber some 8 feet in diameter, held under normal conditions within a water-tight compartment by means of a stout screw carried through the base. At one spot within the water-tight compartment is a secondary chamber containing a buoy attached to a length of wire. On an accident happening to the submarine, the crew enter the water-tight belt, and, sealing the door behind them, pass on to the inner cylinder. One stays behind sufficiently long to release, by means of a bevel gear, the buoy in the smaller chamber. The buoy rises to the surface at once, and indicates the whereabouts of the submerged craft. As soon as the crew are within the inner cylinder and the doors are shut, the cylinder is released from its contact with the body of the submarine by the unscrewing of the grip beneath the floor. If the compartment in which the cylinder rests has not been damaged, the cylinder at once rises to the surface by its own buoyancy. There is an electric light in the conning-tower and an apparatus for firing distance-rockets, so that, whether by day or night, attention can be called to the position of the floating cylinder, with a view to obtaining help and avoiding collision. In calm weather, a collapsible boat can be launched through the conning-tower, to enable help to be sought from the shore or from passing vessels, or to locate the search-vessels which might be sent out to look for the submarine. Provision has been made, however, for the contingency of such damage to the submarine as may prevent the lifeboat cylinder from rising to the surface and cause the detention of the crew at the bottom of the sea. Within the cylinder are two other compartments, which can be opened to the sea by a convenient gear. These contain buoys which, rising to the surface, carry with them air-tubes, electric light and telephone wires. The buoys are so shaped that they ride on the waves and keep a free air-vent, and on the exhaust-pipe of one buoy there is fitted a siren. By pumping fresh air in through the other buoy and the foul air out again through this one, the siren is worked, and the attention of passing or search-vessels called to the spot. In proximity to the [illegible]

(Concluded on page [illegible].)

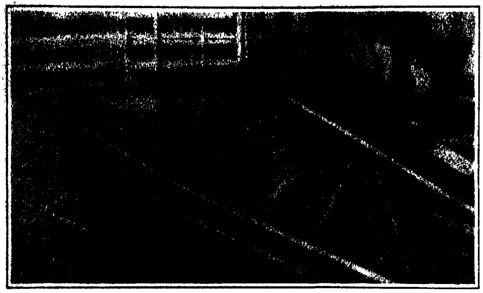


The small drawing in the upper lefthand corner shows the watertight escape scuttles which are fitted to each compartment, as well as to the towers The detail drawing in the lower righthand corner shows the signal apparatus, which is located on the manhole cover in each tower. The whole is fitted with a cork buoy, which on being released, rises to the surface, taking with it a fine flexible wire, by means of which it is possible to communicate telephonically with those imprisoned in the towers Beneath the cover is an alarm.

The Castle device for saving men from sunken submarines.



Over the skeleton is laid one skin of ¼-inch spruce. On the bottom of the forepart two skins of ¼-inch spruce are screwed to the floors.



The structure of the hull, here shown upside down, comprises the usual stringers and ribs to give it strength and form, as in standard boat architecture.

The Rodman Wanamaker Transatlantic Flier

Glenn Curtiss's Masterpiece in Flying Boats

By Our Staff Correspondent at Hammondsport

Illustrated with Photographs Copyrighted by H. Benner

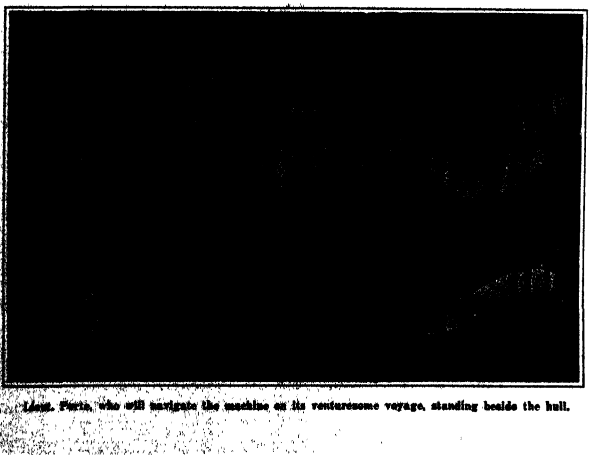
THE Wanamaker transatlantic flier, publicly announced as a serious project early last February, in Mr. Rodman Wanamaker's letter to the Aero Club of America, is now approaching trial as a splendid reality. It represents, as did the great Deperdussin racing monoplane which amazed and delighted aero sportsmen in 1912 the capital achievement of a magnanimous and liberal patron of aviation, a bold, original, and severely practical aeronautical designer and manufacturer, a skillful, sagacious, and fearless pilot, all striving together for the same great end—in the present case, the joining of the hemispheres by a new route of less than one day's sail. The third man of this trio, Lieut. John Cyril Porte, R. N., of England, has been Mr. Curtiss's industrious colleague in working out the details of the huge aeroplane, and in devising the means to navigate it with precision and security.

The original plan, which for the present has been superseded by one requiring less unfamiliar construction, contemplated a tractor biplane with one direct-connected 200 horsepower engine, a whale-shaped or stream-line fuselage with detachable running gear, provided with a water screw for voyaging in the sea in case of necessity, and a closed hood and water-tight compartments for the safety of the two aviators. This craft was to rise from St. Johns, Newfoundland, leaving behind the chassis, soar aloft two miles, take the permanent easterly wind of 50 miles an hour, and, with her own speed of 60 miles, sweep straight to Ireland without a halt, at a speed of 110 miles per hour, and make the entire journey in some 18 or 20 hours.

How the Original Plan Was Changed.

The original plan would not permit of rising from midocean. It was therefore decided to employ, in the first cruise across the Atlantic, an enlarged Curtiss flying boat, capable of carrying two passengers and supplies for twenty-some hours, and, of course, capable of landing and rising at will in mid-ocean in favorable weather. In this later plan no attempt to use the upper stream of the atmosphere would be made. The start would take place when the weather forecast, especially made for the occasion by the U. S. Weather Bureau, should seem most auspicious, and the flight would be made over the most direct and practical route, now high now low, as circumstances should dictate. The transatlantic flier, now receiving its final touches in the Curtiss factory, is by far the largest aeroplane ever built in the United States, and one of the very largest in the world Sikorsky, in Russia, and Collieux, in France, have machines—the former a land, the latter a water craft—which can carry larger loads; but they were not designed for such long distances, and could not carry sufficient fuel to attempt a flight across the ocean Sikorsky's machine, for example, has motors aggregating 400 horse power, and would need two tons of supplies to clear the Atlantic securely without stop

The fore part of the hull, forming the storage-room, is shaped like a slipper; the after part is shaped like the rear end of a whale.



Lieut. Porte, who will navigate the machine on its venturesome voyage, standing beside the hull.

The Wanamaker craft is a biplane flying boat, measuring 72 feet from wing tip to wing tip of the top plane, and 46 feet in the bottom plane; 38 feet from prow to the end of the vertical rudder, spreads about 500 square feet of wing surface, and weighs complete, with two men and supplies, about 5,000 pounds. The wings are 7 feet wide, and have a gap between them of 7½ feet The hull is 34 feet long, [illegible] feet in the beam 6½ feet deep from keel to top of hood, and generally of the Curtiss flying boat pattern, but with a closed hood provided with numerous small celluloid windows over its top and around its front and two sides, on the level of the eyes of the aviators sitting on the bench in the fore part of the cabin

Some of the Craft's Interesting Features.

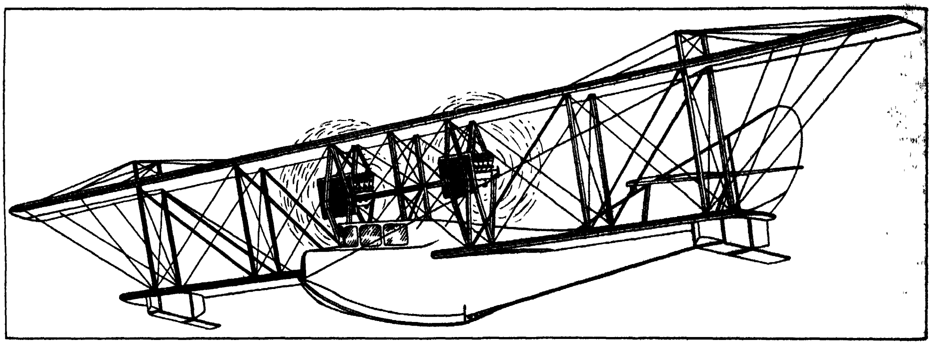
The fore part of the hull, forming the storage room and pilots' cabin, is shaped like a slipper, the rear part is shaped like the rear of a whale. The whale-like stern carries the horizontal and vertical control surfaces. The craft is propelled by two engines mounted midway between the planes, on either side of the hull, each directly connected to its individual propeller. The control system differs from the usual Curtiss type only in the manner of working the ailerons. On account of the great force required for this, the ailerons are worked with the feet. Thus pushing with the right foot elevates the right aileron, thereby depressing the right wing, and *vice versa.* When the boat runs quickly along the water, it gradually rises, skates on the sole, then on the heel of the slipper, then soars aloft, the whole craft beaming scarlet, to be more clearly visible at a great distance. Such is a general description of the more striking features of the strange vessel that is to take the modern Columbus from the New World to the Old World.

The structure of the hull is fairly indicated in the accompanying illustrations. Its skeleton comprises the usual stringers and ribs, to give it strength and form, as in the standard boat architecture. Over these is laid one skin consisting of ¼-inch spruce laid lengthwise, with slight upward spiral toward the stern, and fastened on with brass screws. On the V bottom of the slipper-shaped fore part of the hull, two skins of ¼-inch spruce are screwed to the floors, or V cross-members, with blind holland laid between skins, and saturated with marine glue. The entire hull, thus framed and covered with ¼-inch spruce, has placed over it two layers of blind holland, the under one laid lengthwise, the next one wound on spirally, both brushed with marine glue, ironed hot, and finally painted. The prow is sharp vertically—a new departure—to cleave the waves and to avoid shipping water; the stern is oval, terminating in a vertical edge to which the rudder is hinged.

The interior of the hull aft the step has four water-tight compartments separated by vertical cross-partitions of three-ply birch veneer 3 millimeters thick. Before the step is the large compartment, or cabin and supply room. Its rear part contains three gasoline tanks having an aggregate capacity of 1,500 gallons, all of circular section and made of tinned steel. From these tanks the fluid is pumped up to the auxiliary or feed tanks, from which it runs by gravity to the engines as needed. In the forward part of the cabin, a bench with a back stretches quite across the boat, and has a 3-inch deep corduroy cushion to make the aviators comfortable. Behind this seat is a mattress whereon one at a time can recline or sleep, if advisable. Before the seat are the navigating instruments and the usual two-wheel Curtiss control.

The Wings of the Machine.

The over-all dimensions of the wings have been given. Their contour is that of the most efficient practical wing resulting from the systematic aerodynamic investigations conducted by the British government in its aeronautical establishment. The contour measures 7 feet in chord, 6 inches in depth of camber of its upper side one third back from the leading edge, is nearly plane or straight underneath, and dips sharply down at the forward edge, like the edge of a bird's wing, or like the wing patented by Phillips in England thirty years ago. The rear edge of the wing is somewhat flexible. Two main spars in each wing, of I-section, run throughout its entire length, and each is placed about 18 inches from the nearest wing edge. The front edge of each wing is formed of a rounded beam, approximately crescent-form. Practically all the wing woodwork is of spruce, and the internal structure, as a whole, is trussed with piano wire, according to standard good practice. The whole wing and tail surfaces are covered on both sides with a light Japanese silk, and varnished several times to make it air-tight. Near the hull the wings are so strongly ribbed and covered with veneer as to bear the weight of a man, but farther out they are built of ordinary strength. Heavy stream-line posts and heavy steel cables truss together the upper and lower planes.



The craft is a biplane flying-boat, measuring 72 feet from wing tip to wing tip of the top plane and 46 feet in the bottom plane, and 38 feet from the prow to the end of the vertical rudder. The wing spread is about 500 square feet. The machine will be driven by two 90 horse-power eight-cylinder engines.

The upper planes jut about 18 feet beyond the lower ones at each side, and in this over-shoot they are cut away to the rear of the back spar, so that the ailerons may be attached there. These measure 15 feet long by nearly 20 inches deep, and turn only upward.

The engine section of the wings is peculiarly massive in structure and appearance. The lower wing spars pass through the hull, like floor joists in size, and are firmly lashed to the interior with strong ash verticals joined to them with angle iron. Each engine is supported on a massive wooden frame, sustained front and rear by a double post whose two parts are spread out, diamond-shape, and trussed like a crutch, for strength, and worked to stream-line form. The distance between the two propeller shafts is 8 feet 8 inches. The whole engine section is trussed with heavy cables, has a massive brace running obliquely down and forward into the cabin, and, as a whole, presents more the appearance of a pavilion for resisting storms than a craft to soar on thin air.

The Engines of the Flier.

The two engines are of the best Curtiss O. X. make, each of 90 horse-power, eight-cylinder water-jacketed, and running at 1,200 revolutions; they weigh, together, 690 pounds. Their radiators weigh 62 pounds each. Each presents 2 square feet of front, contains ¼-inch tubing nearly 3 inches long, and the radiator of each exposes 100 square feet of cooling surface. In the 30-hour continuous test, held the second week in June, the engines consumed together 288½ gallons of gasoline and 10⅝ gallons of oil, weighing in all about 1,800 pounds. The radiators will be placed before the engines, and the oil tanks just behind the radiators, all midway between the upper and lower planes. Bosch magnetos and carbureters complete the power plant.

The tail unit, mounted on the rear of the hull, comprises an adjustable tail plane, of some 50 square feet surface, and semi-circular in form, to the rear edge of which is hinged the elevator, of the same area; also a fixed vertical triangular fin to whose rear edge the vertical rudder, of some 20 square feet area, is hinged.

The propellers may be the ordinary two-bladed wooden screws, of 8 feet diameter and 5 feet pitch, or some new kind not yet made public.

Lieut. Porte, after receiving the Wanamaker flier from Mr. Curtiss, at St. Johns, Newfoundland, will be in command of her during the over-sea voyage, aided by an assistant who is a skilled aviator expert in knowledge of the Curtiss motor. Mr. George Hallett will act as chief aviator, while Lieut. Porte will be the responsible navigator in authority. Mr. Hallett will be dropped at the Azores, and John Lansing Callan, one of the instructors in the Curtiss flying school, will there board the machine and complete the trip with Lieut. Porte. Mr Hallett and Mr. Callan will relieve Lieut. Porte at the controls.

Space will not permit a description of the navigating instruments and the preparations for safety and success during the voyage. The instruments have been carefully studied, some being new to the art; arrangements have been made for assistance, if needed, *en route*; the exact route itself, and the nature of the difficulties to be met during the daring voyage, have received due attention. It is to be hoped that these details, many of them still secret, have been as well provided for as has the construction of a motor qualified to sustain a continuous voyage of a day and a night—and that the final test of Lieut. Porte's navigating provisions will be as felicitous as the 30-hour test of those stanch Curtiss engines.

Regulations for the Round-the-World Flight

REGULATIONS governing the [illegible] aerial race of the Panama-Pacific International Exposition have been submitted to the Aero Club of America.

The race, for which $150,000 will be awarded as prizes, will start from the Panama-Pacific Exposition grounds in San Francisco on May 15th, 1915. It must be completed before noon of December 4th, 1915. Licensed pilots of any country may compete, [illegible] kind of aircraft may be used. The entries [illegible] ceived between November 1st of this year [illegible] of next year. An entrance fee of $500 [illegible] pany each entry.

All competitors must pass over the course in [illegible] erly direction, and controls will be designated [illegible] exposition authorities, at which each competitor [illegible] alight in the order named. Each flier will [illegible] log book and instruments to the officials [illegible] each control. Each competitor may follow any route he chooses from one control to the next, but supply stations and patrol service will be provided along only one route, the one considered most feasible.

The distance between two controls must be traversed in the same aircraft. A stop may be made anywhere, however, for repairs, even to the extent of installing new motors, and at any control the competitor may abandon the machine he has been using and go on with another one, if it be of the same class of aircraft as that in which he started the race.

Of the $150,000 prize money, $100,000 is to go to the flier finishing first, $30,000 to the second, and $20,000 to the third, provided the flight is made within 121 days. If the first flier fails to make his way around the world within 121 days, but does it on or before December 4th, the first prize will be reduced $1,000 a day for each day more than the 121 required to finish. Reductions are to be made from the second prize at the rate of $300 a day, and for the third prize at $200 a day.

If none succeeds in the flight, but one or more do it all except across the Atlantic and Pacific oceans, or any other body of water, there will be a reduction of $20 from the first prize for each nautical mile not traversed; $6 from the second prize; and $4 from the third. These deductions will be in addition to those for time over 121 days.

Arrangements are made for third, fourth, fifth, sixth, and seventh prizes in case the deductions from the first, second and third prizes make them possible. No prize shall be paid to any one who does not finish the race before December 4th. Fliers may carry aids or passengers and may change them *en route*, but the pilot of record must be in control at all starts and alightings.

Another Zeppelin Accident

ANOTHER of the Zeppelin airships of the German army, the "Z 1," was badly wrecked near Diedenhofen, on June 13, according to press dispatches. While trying to effect an emergency landing the air cruiser broke at right angles behind the rear car. A lieutenant was injured.

The accident occurred during a flight from Cologne to Metz. The "Z 1," with a military crew on board, ran into a rainstorm and the commander decided to descend. When the air vessel was within a few yards of the ground a sudden gust of wind dashed it violently to earth and it broke virtually in two. The airship can probably be repaired.

Color Music

To the Editor of the SCIENTIFIC AMERICAN:

My attention has been drawn to the SCIENTIFIC AMERICAN, dated February 21st, pages 163-170, in which appears an illustrated article entitled, "An Organ on which Color Compositions are Played: A New Art of Color Music and its Mechanism," by John W. N. Sullivan, and I have read this with very considerable interest.

In this connection I might mention that Prof. Rimington and myself have been workers in this sphere, unknown to each other, and I registered my patent in the Commonwealth of Australia on January 22d, 1912. I have since obtained a patent in Great Britain for "Color Music," dated December 28d, 1912, No. 29615/1912.

Sun-power Plants Not Visionary

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of May 23rd of this year appears an article headed "Energy from the Sun," in which you have expressed yourself too pessimistically.

The only invention claimed in the Egyptian sun-power plant is the *generating of steam by the heat of the sun*, and only the amount of steam generated should be taken into consideration.

Unfortunately, there were serious mistakes made in the shop work of the construction of the engine and pump, which did cut down the amount of pump horse-power delivered to 19.1. These mistakes would have been avoided had we tested the engine and pump at the works before sending them to Egypt, and will not occur again.

The sun heat absorbers generated steam enough to give *an average* of 50 brake horse-power for ten hours a day, as will be seen if Mr. Ackermann's tests are read by taking into consideration only those tests which were made at 15 pounds absolute (the pressure at which the sun heat absorbers are to run).

We are, therefore, right in calling this steam-generating plant one of 50 horse-power instead of 19.1.

Now a careful estimate by an experienced builder of power plants shows that the steam-generating portion of this plant can be duplicated and erected in the tropics when done on a manufacturing scale by special machinery, for the sum of $7,800, or $156 per brake horse-power.

It is entirely true that this is considerably more than the cost of the best modern steam plants of equal power, but it must be borne in mind that when this plant is once erected, it not only furnishes the required power *perpetually*, but may be said to "*raise its own coal*," and this puts the sun-power plant in an entirely different class, and justifies most careful thought.

The plant is so constructed that it has a very long life and requires little repairs, and is, in fact, very simple.

It is true that sun-power plants do occupy a great deal of ground, but ground in those portions of the tropics where we at present intend to confine ourselves has practically *no value*, and therefore it is merely a matter of cost of construction, maintenance, and cost of running.

Maintenance and cost of running is a little less than that of an equal power coal plant, and therefore the comparison narrows itself down to a matter of interest on the increased investment, and careful figures show that, taking this into consideration, we can compete with coal at $2.50 per ton in those portions of the tropics where the sun shines practically throughout the year.

For the next ten years or so we expect to confine ourselves to irrigation in those regions of the tropics where coal is $15 per ton and above, and where we can count on at least 90 per cent of sunshine during the days of the year, and there we *know* our present sun-power plants will effect great savings. This field alone is large enough to give us all the work we shall be able to handle for some ten years to come.

We have devoted seven years of time and have spent nearly a quarter of a million dollars in investigating every possible phase of sun power, and firmly believe we have solved the problem of utilizing, for the benefit of the human race, this greatest of all natural forces, and ask all engineers to look at this great problem from all sides, and very carefully, before putting it into the visionary class.

The problem of flying in the air has been nearly solved, but only fifteen years ago it was called a dream of the far-distant future.

Up to the present time in all the history of the human race, only three natural forces—wind, water, and fire—have been utilized, and it is about time that all thinking men should seriously occupy their minds with utilizing the greatest, the cause of them all—the sun.

Certain it is that it must be done within the next one hundred years or so, or else we shall have to revert to barbarism, because eventually all coal and oil will be used up.

Sun power is most logical. We know the sun is the central power-house of our universe, and we should, therefore, attack most seriously the problem of connecting ourselves with the sun *direct*.

Please do not take our attempt as the final. Natural forces are not entirely conquered in a few years. The first steam engine was not a quarter as efficient as our present ones. We know quite well that we have only made the beginning, and that the sun-power plant of ten years hence will be at least *twice* as efficient as the one we have just tested, and that improvements will be made every year, but someone must make a beginning in a practical and *public* way, and we have done this to the best of our ability.

London, E. C., England.

The Ease of Variable-star Observing

To the Editor of the SCIENTIFIC AMERICAN:

Your issue of April 4th, 1914, contained an excellent article, "The Attractions of Variable-Star Observing," by Dr. Edward Gray. It savors somewhat of presumption to attempt to supplement Dr. Gray's word, but it struck me possibly the Doctor had not sufficiently emphasized the ease with which this work may be taken up by the beginner. It occurred to me, therefore, that the very fact that Dr. Gray is one of the pioneer amateur observers of variable stars, while I am but one of the very "new beginners," might place me almost in a better position to demonstrate to other beginners how easily they can make a start at this fascinating form of useful observing. A bald recital of my own recent experiences may perhaps prove my point.

The possession of a good small telescope (a 3-inch objective) had for about a year and a half been a source of great pleasure. But "sight-seeing," even in the heavens, grows monotonous, and the trip to the roof of a New York apartment house, my only "observatory," became more and more laborious. Finally, the telescope remained for weeks at a time untouched—a stagnant investment. It was but a few months ago, having but a vague idea of what a variable star was, that I wrote to the secretary of the American Association of Variable-Star Observers, Mr. William Tyler Olcott, Norwich, Conn., asking for information as to how to begin, and for help in beginning, variable observing. Promptly, I received a most explicit reply, together with a number of variable charts, and that very night, with no difficulty, picked up several fields and recorded several observations. This certainly shows that a start is not hard to make, even for the veriest tyro. A letter to the Harvard College Observatory brought an equally prompt response in the form of some of the observatory bulletins describing how best to make observations, accompanied by several more charts. Since then the secretary of the association has, from time to time, in fact, every few days, added charts to my list, until this comprises well over one hundred different ones. As a result, my telescope, far from standing idle, finds every clear night a definite, interesting, and constantly new work to do

My equipment is of the simplest; a 3-inch telescope, without even a "finder"; a pair of field-glasses, a star-atlas, price $1, and the charts supplied with no cost to me. Many observers have telescopes mounted equatorially, and having "circles," which enable them to "set" on a variable field immediately. For them, I have almost a feeling of pity—they lose the delight in "sweeping" a region in search of a variable-field and at last locating it, which method, although it often requires more time, bears with it a joy much akin to the "Easter-egg hunting" of our childhood. The feeling that one is "growing warmer," the sudden recognition of some small configuration of stars marked upon the chart, and the final most satisfactory "*There's* the variable," can never be experienced by the more scientifically equipped.

Using, by necessity, this less scientific, but I insist this more sporting, method, the first move is to mark on the star-atlas the position of the variable, or, rather, the variable-field, this being always given on the chart itself. The relation of this position to the naked-eye stars shown on the atlas enables the observer immediately to sight his instrument at *about* the correct position, and then a few moments' careful "sweeping" identifies the variable. Surely nothing can be much simpler. It is true that sometimes a field will prove most elusive, but care and patience always are successful, and the pleasure in finally triumphing is perhaps even increased by the difficulty. It is also true that, after but very little practice and a consequent knowledge of the positions of the fields, a variable is found at the first sight, and the sweeping search is unnecessary.

Once in the field of view, it requires but the most brief experience to compare with good results the brilliancy of the variable with the various standard comparison-stars, whose magnitudes are marked on the chart. Some care must be used in making estimates of deeply-colored stars, which often appear too faint upon first sight, and whose true brilliancy is not recognizable until their light is allowed to "sink into" the eye; but, at the most, three or four minutes is ample time to obtain an estimate of magnitude often of remarkable accuracy.

The use of the field-glass becomes practical in many cases where variables wax high enough in magnitude to make the greater light gathering power of a telescope unnecessary. I have often found my field-glass available as a substitute for a "finder," which my telescope lacks. Where, particularly in our hazy New York skies, it is impossible to see with the naked eye the fainter stars marked on the star-atlas, especially when these stars are included in the variable-field, the field-glass can be of great assistance.

Dr. Gray pointed out most clearly the fascination and the real value of this variable observing, but it does not seem out of order to reiterate that it is practically the only steady, useful work which amateurs can do with small instruments. It is gratifying to know that the work is much appreciated by the Harvard College Observatory, the headquarters in this country for this branch of astronomical research. Recently, the director has placed in the hands of the secretary of the association a large number of variable charts for distribution among the members of the association, and in his latest report the work of the association is spoken of in a most complimentary manner.

It is to be hoped that the membership of the association will continue to grow in numbers as rapidly as it has during this past year. More observers are needed—there cannot be too many—and anyone possessing an instrument with an object-lens of two inches or over will certainly find the work well worth undertaking They may be sure, also, of a warm welcome to the ranks of the variable observers, and of obtaining all the assistance which lies in the power of the members to give.

EDWARD W PUTNAM.

A Chance for Some American to Build an Iron Foundry in Poland

ONE of our European subscribers sends to us the following inquiry.

"We intend to erect a steel and iron plant in this country, and we request you to indicate what firms would be willing to consider our needs, the following general specifications to be observed.

"1. The iron plant is to have a yearly production of about 11,500 tons. Of this output 6,560 tons are intended for the production of water collar and bowl pipes; 1,640 tons for fittings to these pipes, and 3,300 tons for casting various machine parts, such as transmission wheels, gears, parts of water turbines, aqueduct piping, special machinery for sugar and other plants.

"2. The steel foundry is to have an annual production of about 6,600 tons. Of this output 3,300 tons will be used for producing blocks for hydraulic presses and hammers, rollers, etc., and 3,300 tons for various steel castings, such as railway car wheels, parts of railway cars and locomotives, gear wheels, bridge members, parts for high-pressure steam engines, rollers, and sundry small castings.

"3. In order to carry on the operations described, we intend to erect one Siemens-Martin furnace having a capacity of about ten tons of metal and shops for general work in which the following departments are to be found: *a*. Manufacture of water turbine parts; *b*, manufacture of water pumps, *c*, railway car wheel shop; *d*, gear wheel shop for turning out cylindrical and conical gears as well as Wuest's and Cytroen's gears."

The SCIENTIFIC AMERICAN will be pleased to place American manufacturers and engineers in communication with our correspondent.

An Honorary Degree Conferred on the Commissioner of Patents

HON. THOMAS EWING, Commissioner of Patents, received the honorary degree of Doctor of Laws from Georgetown University. Dean Breeden in conferring the degree characterized the Honorable Commissioner of Patents as "a man of action who attained such eminence as drew to him widespread attention, and deserving of the high post of public office"

A French Entry for the Transatlantic Flight

THE French aviator, Auguste Maicon, has been entered for the *Daily Mail's* transatlantic flight for a prize of $50,000 by Paris Singer, a wealthy American resident of Paris, at his own request

Mr. Singer, who employs Maicon in his "aeroplane stable" at Cap Ferrat, will finance the venture.

The Challenger "Shamrock IV" Under Sail

New Yacht Easily Outsails Fastest British Cutter in Moderate Winds

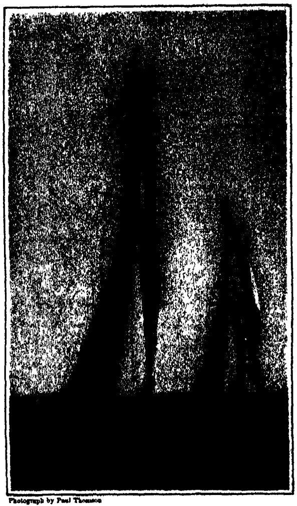
Elaborate trussing of "Shamrock's" mainmast.

NOT until "Shamrock IV" meets either the "Resolute" or "Vanitie" next September on the Sandy Hook course, will anybody, not even the men who designed the boats, have the least idea which is the faster of the two. There is no question whatever but that both Herreshoff and Gardner have turned out, in the 75-foot class, two boats which could easily save their time allowance over "Reliance," and, under certain conditions of wind and weather, such as light airs and a tumbling sea, might beat the 90-foot yacht with time allowance excluded. If proof of this were wanted, it is sufficient to point to the first of the three trial races held recently over the Sandy Hook course, in which the winner, the "Resolute," made the thirty miles to windward and leeward in the record time of 3 hours, 15 minutes, and 41 seconds. To appreciate the significance of this, we must remember that the next fastest time, 3 hours, 24 minutes, 39 seconds, made by the 86-foot "Vigilant" against "Valkyrie II," was done under the favorable conditions of a strong wind of about twenty knots; whereas "Resolute" made her record in a wind which varied from say ten to fifteen knots in strength. At the present writing, "Resolute" seems to have taken the measure of "Vanitie" going to windward, for she beat her in this particular race 3 minutes and 49 seconds, in the fifteen miles to the outer mark, and in the third race she beat "Vanitie," in ten miles of windward work, by 4 minutes and 1 second. On the other hand, "Vanitie" is considerably faster than "Resolute" in reaching, for in the second race, on a reach of ten miles, she outsailed the "Resolute" by 4 minutes and 20 seconds.

But what about "Shamrock IV"? Has Nicholson succeeded in getting the same speed out of a 75-footer as we have on this side of the water? The only measure of her speed is the old "Shamrock," also a 75-foot yacht, with which Sir Thomas Lipton made a pretty clean sweep for some years past in the 75 foot class in European waters.

It should be explained that this "Shamrock" is not one of the old challengers for the cup, for each of these went to the scrap pile long ago. The "Shamrock" was built in the new 23-meter (75 foot) class several years ago, under the International Rule, the object of which was to provide a fast racing yacht which would be of strong construction, habitable, and suitable for cruising purposes if it were desired so to use her. This rule was drawn with the object also of cutting out the long, full overhangs and the shoal skimming dish hull and keels of exaggerated draft, which characterized "Reliance" and to a lesser degree, "Shamrock III." The rule tends to produce a boat similar to "Resolute" and "Vanitie," and it is probable that the underwater form of the old "Shamrock" lies somewhere between that of these two boats. At the same time it must be remembered that, since "Shamrock," under the International Rule, had to be built to Lloyd's requirements as to scantling, etc., she is probably much heavier in build than either of our cup defenders, and therefore, presumably, she is not so fast. On the other hand, the "Shamrock" holds the record for speed for a 75-foot cutter, and indeed, as far as we know, for a cutter of any length over a 48-mile course. This achievement she put to her credit in a hard-sailed race over the inside course off the Isle of Wight, in which she covered just under 48 miles in exactly 4 hours, which means that she must have maintained an average speed of slightly under twelve knots.



Photograph by Paul Thompson

The 23-meter "Shamrock" (right) trying out "Shamrock IV."

This race, of course, was sailed in a very strong wind, and, thus far, in the trials between "Shamrock" and "Shamrock IV" there have been no tests of exactly this character. On the other hand, if the cabled accounts are correct, Lipton's new yacht defeated the old "Shamrock" over a triangular course of fifteen miles by 9 minutes and 4 seconds. The most significant fact about this race is that she beat the old boat 6 minutes in five miles of windward work, or over a minute a mile. Over a windward and leeward course of fifteen miles, out and back, this would mean a gain of over 18 minutes at the outer mark.

These results are so extraordinary, achieved as they were against a well-proved boat of the same class and same length, that we feel inclined to doubt the accuracy of the timing or the distances. Nevertheless, it is well established that "Shamrock IV" is a remarkably successful yacht in working her way out to windward. Also, she is said to have beaten the old "Shamrock" almost as much as a minute a mile when running down the wind in a light breeze. On a reach, however, she does not show much superiority; and it is on this account, doubtless, that "Shamrock IV" is to be given a double head rig (jib and staysail) in place of the single jib which she has hitherto carried.

To our mind the most significant fact regarding Lipton's new boat is that, in light airs she has not shown much superiority to the old "Shamrock," this being due to the fact that, because of her full body and unusually long keel, her wetted surface must be very large for a 75-footer, and as the wind lightens in strength, the area of wetted surface becomes a most important factor. In spite of her large sail area, it is probable that the ratio of sail area to wetted

(Concluded on page [illegible])

Repair of Los Angeles Aqueduct Siphon

Collapsed by Atmospheric Pressure; Restored by Hydraulic Pressure

By Burt A. Heinly

A PECULIAR accident which is at once a striking illustration of the terrific force of atmospheric pressure and at the same time the counteracting effect of hydraulic pressure was that which brought the rupture and repair of the Antelope Valley steel inverted siphon of the Los Angeles aqueduct, in the period extending from February 20th to March 18th, 1914.

The Los Angeles aqueduct, the 233-mile watercourse by which the city of Los Angeles is to procure its domestic water supply from the Sierra Nevadas, crosses the Antelope Valley at its upper end, about one hundred miles northwest of Los Angeles, in the shape of a concrete and steel pipe with a total length of 21,685 feet. The concrete approaches end where the head exceeds 70 feet, and their total length is 6,149 feet, leaving 15,536 feet of steel pipe, 10 feet in diameter, with a head ranging from 70 feet to a maximum of 200 feet. This line was completed in the Fall of 1912 at a cost of $249,200, and is claimed by engineers of the Los Angeles aqueduct to be the longest line of pipe of such large diameter in existence. The thickness of the steel ranges from ¼ inch to ⅝ inch.

On the night of February 20th, following three days of heavy rainfall, the two concrete piers supporting the siphon at a point near the center of the valley, where the line crosses a ravine, were undermined and fell on their sides. The siphon which was in operation at the time was ruptured, permitting the water to flow out under a very high velocity. There then followed a collapse of 10,000 feet of the siphon. The line lies half buried in the ground, so that the under half was uninjured, but the upper half was driven in with such great force that the upper semi-circumference was bent downward, in many places, to within a few inches of the lower semi-circumference.

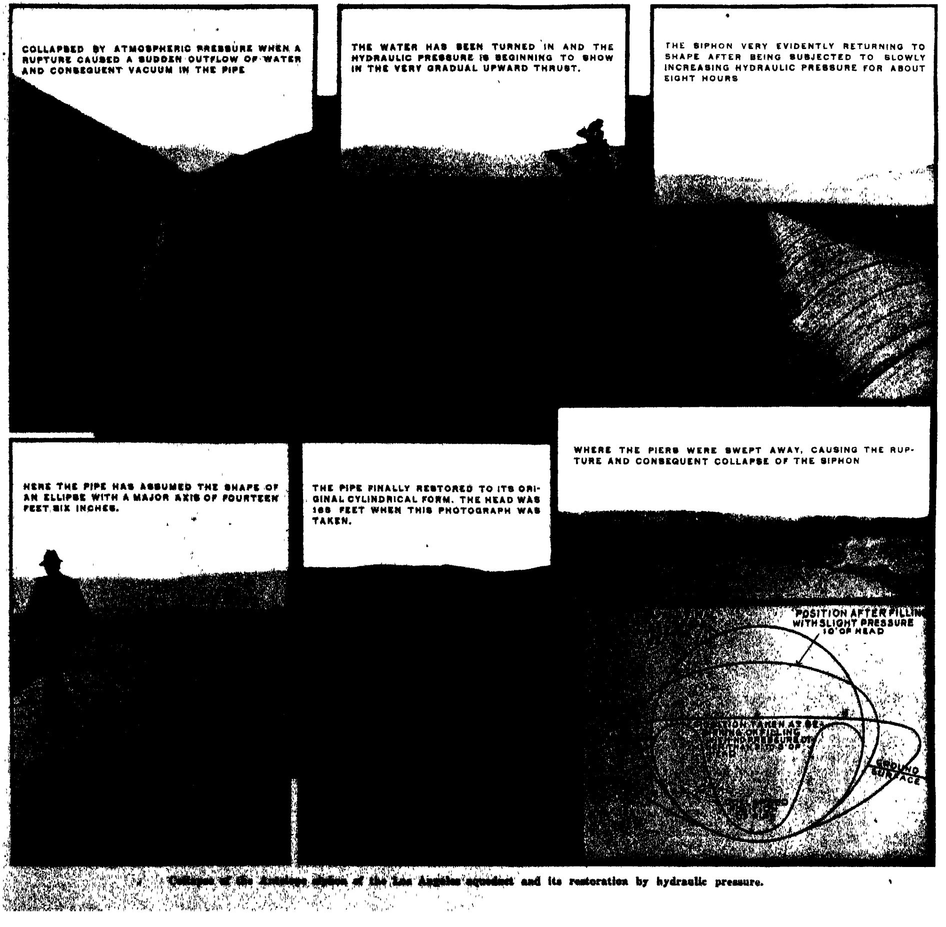
At a point 400 feet from the northern or inlet end of the steel pipe, several of the plates were torn and the rivets sheared, the rupture at this end not being fully explained. The pipe was open at both ends, allowing the free entry of air. There were no summits in the pipe and no air valves were installed. The concrete approaches, and the ⅝-inch plate, were uninjured.

The pipe, on the morning after the mishap, had a "U" shape as shown in the illustration. Its rehabilitation by water pressure, while simple in the extreme, is noteworthy on account of the magnitude of the work, and has attracted the attention of the engineering world.

Under the direction of the chief engineer, Mr. William Mulholland, new plates to replace those torn, were rolled, sheared, and punched, transported by wagon 35 miles across the desert to their destination and riveted into place. New piers had been constructed in the *interim* to replace those which had been washed away.

The aqueduct was then placed in operation. A flow of 750 miner's inches, 405,000 gallons per hour, was then turned in. Under a head which at first did not exceed two feet, the heavy steel plates, upon which steel hammers had had little effect in the attempt at straightening, began very slowly to "iron out." As the pressure was slowly permitted to increase, with a gradually added flow up to 2,000 miner's inches, 1,080,000 gallons per hour, the pipe assumed what will be to the layman the unusual shapes shown in the accompanying diagram, until it returned to its truly cylindrical form. At one time, it assumed the shape of an ellipse with a major diameter of 14 feet 6 inches

To the engineer it will be interesting to know that in this transition, none of the longitudinal seams were sheared and that only a small amount of caulking of the last named seams was necessary In some instances, for distances of 400 or 500 feet at a stretch, the return to rotundity was made with no damage whatsoever to the pipe. At other points, only the caulking tool was required. For repairing the damage due to collapse, the expense did not exceed $250, and for the whole work of repair, which included cost of and fitting in the new plates, building concrete piers, and preparing against the repetition of the accident, the amount expended was within $2,200.



COLLAPSED BY ATMOSPHERIC PRESSURE WHEN A RUPTURE CAUSED A SUDDEN OUTFLOW OF WATER AND CONSEQUENT VACUUM IN THE PIPE

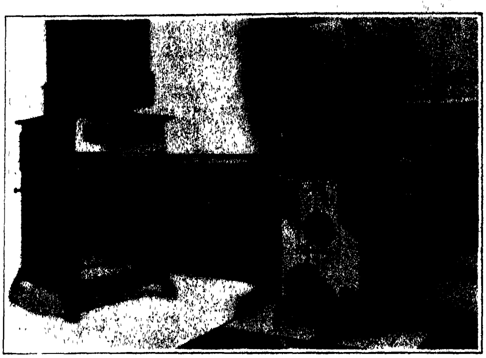
A New Rotating Sleeve Motor

A NEW motor of the non-poppet valve type has just appeared in which a single sleeve acts as a valve, whereas practically all other motors of the sleeve valve type have two sleeves. This motor also differs from others in the fact that the sleeve revolves continuously at one quarter crankshaft speed. A few years ago a rotating sleeve motor was introduced from France, but the present motor differs from that in the fact that it has a stationary sleeve, or cylinder, around which the rotating sleeve operates. An important feature of the new motor is that both the stationary sleeve or cylinder and the rotating sleeve may be removed readily from the water-jacket without the necessity of disassembling the engine and separating the cylinder from the gear-case in order to reach the sleeve. Not even the timing of the gear is disturbed in removing the cylinder or the sleeve valve.

The improved motor is made up of four principal parts. Outside there is the common cylinder casting, containing the water-jacket portion. Within this is placed a fixed sleeve with enough clearance around it to receive the rotating sleeve Last of all, comes the piston, which reciprocates within the fixed sleeve In the photograph showing the various parts, the rotating sleeve is indicated at *A*, the fixed sleeve, or cylinder, at *B*, while the third view shows the sleeve, the cylinder, and the gearing assembled. The sleeve *A* is connected with a spiral gear *G* by means of square-jaw clutches. The gear *G* is engaged by a spiral pinion *P*, mounted on a shaft that lies parallel with the crankshaft The valve shaft is driven by geared connection with the crankshaft, as shown in the photograph of the motor with the cover of the gear-case removed The sectional drawing shows how the gear wheel *G* is clamped between the bottom of the water-jacket and the top of the crank-case and is not disturbed when either the valve sleeve or the fixed sleeve is removed. The fixed sleeve, which is indicated by a solid black line in the drawing, is formed with an enlarged water-jacketed head that is held in place by means of four bolts. The spark plug is inserted through the center of this water-jacketed head

The revolving sleeve is formed with two rectangular ports *Q* The stationary sleeve, or cylinder, also has two ports, marked *S* and *E*, the former being the intake port, and the latter the exhaust port. These are opened successively at the proper time by the port *Q* in the revolving sleeve *A* Because the sleeve revolves at one quarter crankshaft speed, it must have two ports which alternate in their functions This gives each port ample time to cool, and permits of better lubrication Oil under pressure is supplied to the sleeve through a spiral groove therein.

The timing of the motor is as follows: The intake begins to open at 14 degrees past top dead center, and attains full opening in 82 degrees. Then it remains at maximum opening while the crank travels 28 degrees, closing thereafter in 82 degrees, giving a total range of 192 degrees. The exhaust valve has a range of opening covering 228 degrees, of which 110 degrees is required in obtaining maximum opening. Then there is a continuance of 8 degrees at maximum opening and closing in 110 degrees, thus bringing the exhaust to closed position at 5 degrees past the top dead center. The exhaust starts to open at 48 degrees ahead of the bottom dead center, and the intake starts to open 14 degrees after top dead center, and is closed at 26 degrees past bottom center. These timings have been adopted after careful test to work out a motor which will idle at slow speed and develop maximum horse-power at relatively high crankshaft speed. With this timing on a six-cylinder block motor, with cylinders of 3½ by 5¼ inches, operating at 2,400 revolutions per minute, 55 horse-power has been obtained on a block test. The weight of the motor is but 550 pounds. The motor is lubricated by a force-feed system, with pressure supplied by a gear pump located in the crank-case.



The oven has a one-fifteenth horse-power motor connected by a belt with the fan which maintains a circulating atmosphere within the oven.

Science and the Tariff

By Dr. E. E. Pickrell

DUE to extensive publicity of recent years, everyone realizes that the United States Government employs a scientific means to provide pure food and drugs to the consuming public. But few people are aware that science is a valuable assistant to "Uncle Sam" in the enforcement of the tariff laws in ascertaining the duties on imported merchandise, and that the application of every new tariff is more dependent on science. How many persons realize, when they purchase an article made wholly or in part of imported cotton yarn, or cloth, that the United States Government, in collecting the duties on that article, took into consideration the fact that cotton yarn and cloth are hygroscopic, and the amount of moisture they contain is dependent upon the temperature and relative humidity of the atmosphere? But few have a knowledge that in the administration of the cotton schedule of the tariff act of October 3d, 1913, the U. S. Treasury Department has taken into consideration the moisture content of cotton yarn and fabric. Schedule I (otherwise known as the cotton schedule) of this act provides for cotton yarn and fabric at an *ad valorem* rate of duty and establishes the lines of demarkations of the various classifications, according to the yarn number.

In the ascertainment of the yarn number the weight of the yarn, or cloth, is one of the principal factors. The moisture content, therefore, bears an important relation to the weight, and consequently to the yarn number. The quantity of moisture cotton cloth or yarn contains depends upon the temperature and relative humidity of the atmosphere. As an illustration, let us take a sample of 840 yards of cotton yarn, which under atmospheric conditions of 70 deg. Fahr. temperature and 65 per cent relative humidity, weighs 116.67 grains. The yarn number of this sample is 60, for a No. 1 cotton yarn is a yarn 840 yards of which, under these atmospheric conditions, weighs 1 pound, or 7,000 grains, and a No. 60 cotton yarn weighs 1/60 of 7,000 grains, or 116.67 grains. In this sample the proportion of moisture to dry cotton is as 8½ parts to 100 parts, or 9.14 grains to 107.53 grains.

Expose this sample for a sufficient period of time to an atmosphere of 73 deg. Fahr. and 46 per cent relative humidity, and it would weigh 114.19 grains. Its yarn number would be 7,000 divided by 114.19, or 61.3. The moisture content would be 114.19—107.53, or 6.66 grains, representing 6.19 per cent of the dry cotton. Place the same sample in an atmosphere where the thermometer reads 68 deg. Fahr. and the hygrometer records 97 per cent, and its weight would be increased by 121.95 grains, which is equivalent to a yarn number of 57.4. The moisture content would be 121.95—107.53, or 14.42 grains, which represented in percentage of the dry cotton contained in the sample, is 13.41. It is, therefore, quite apparent that a few degrees in temperature and a variation in the relative humidity has an appreciable effect upon the weight of cotton yarn, and consequently the yarn number.

If, on the day of importation of a consignment of cotton yarn into the port of New York, the thermometer registered 73 degrees and the hygrometer returned a reading of 46 per cent, its yarn number, as ascertained, would be 61.3, and the merchandise, accordingly, classified under paragraph 250 of the tariff act as cotton yarn exceeding 59s to 79s at 22½ per cent *ad valorem*. But, provided the temperature and humidity had been 68 degrees and 97 per cent, respectively, the yarn number would necessarily have been 57.4, and in the classification of the importation, a rate of duty of 20 per cent *ad valorem* would have been assessed as for cotton yarn exceeding 40s to 59s. To avoid these differences of

X-Ray Photographs of Flowers

By John W. N. Sullivan

THE discovery of the remarkable penetrative powers of X-rays has received applications in surgery and medicine for some time. But, in one sense, the X-rays which are produced in the ordinary way have the defects of their merits; they are valuable for their penetrative powers, but for some work these are too marked. It is found that if the X-rays from an ordinary Crookes tube are used for viewing the chest of a man, for instance, then the addition or subtraction of a few articles of clothing makes little or no difference to the resultant photographic image. Such high penetrating rays were found quite useless for obtaining radiographs of such delicate structures as a feather, leaf of a plant, or the petal of a flower.

But it has been recently found that by using a specially designed tube under suitable conditions, giving out the softest possible X-rays, not only could radiographs of such structures be secured, but that they showed sufficient detail to admit of magnifications varying from 10 to 40 diameters. A tube capable of producing these rays was designed by Lindemann, who suggested the introduction into the tube of a window made of lithium glass. Such a window offers but a slight resistance to the passage of the softest X-rays it is possible to produce.

Tubes of this type have been used by radiographers all over the world for several years, but it was not until the last two years that their use in obtaining radiographs of thin transparent objects was fully recognized. Beautiful radiographs of flowers, insects, and opaque objects were first exhibited in England at the exhibition of the Royal Photographic Society held in London in October of last year by Pierre Goby, for which he was awarded a medal.

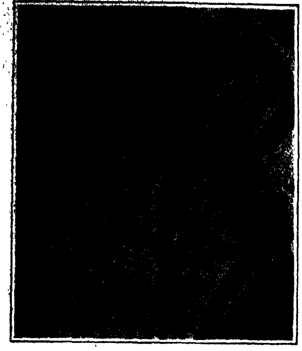
The apparatus for producing such radiographs has since been considerably simplified and the experiments of Hall-Edwards have been made with tubes which had been in use for several months, and with but the addition of a few simple pieces of apparatus, which can easily be constructed by anyone possessing an elementary amount of technical skill.

The tube with which he has achieved the best results is a Bauer heavy anode tube, provided with a Bauer regulator. This tube has been in daily use for months, and the glass is heavily coated with platinum. For ordinary use it requires to be constantly lowered, as it becomes high after a medium exposure.

When working, the vacuum is lowered to such an extent that the cathode stream becomes quite visible, and should it disappear during the somewhat long exposure necessary, more air is pumped in from time to time. For flower studies Ilford X-ray plates are used, enclosed in a couple of Tyler's light-tight envelopes.

The plate is placed at a distance of from three to five feet from the tube, and the proper exposure is learnt by experiment. The flowers, leaves, berries, insects, or small animals are placed upon the envelopes, care being taken that the emulsion side of the plate is uppermost and the tube is placed over the center of the plate.

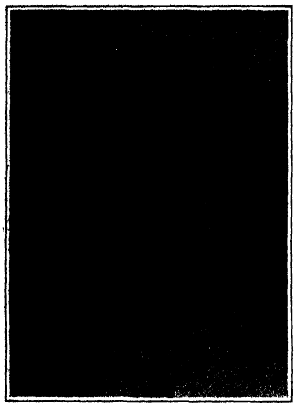
A specimen plate was produced by placing the tube a distance of 8 feet 6 inches from the photographic plate. A twelve-inch coil with a mercury jet interrupter was used. Six amperes from a direct 220-volt supply was passed through the primary, a resistance of about 12 ohms also being used. The exposure was 90 seconds. The negative was developed with a hydroquinone-metol developer, the development taking about 10 minutes.



X-ray photograph of carnations, tulips, and daisies.

Should the flower or other object to be radiographed be of extremely fine texture, it is well to increase the distance between the plate and the tube. In radiographing insects no envelopes should be used, as the grain of the paper is apt to obscure some of the fine details which would be visible without them.

Stereoscopic radiographs may be obtained by first placing the tube 1½ inches from the central line to the right, and in the second case the same distance to the left. The ordinary stereoscopic changing box does not allow the necessary soft rays to reach the photographic plate.



X-ray photographs of anemones.

Micro-radiographs can also be obtained, and Dr. Hall-Edwards hopes shortly to place on the market a simple device for obtaining these with the minimum of trouble and expense.

Inasmuch as these radiographs show the internal structure of flowers, insects, and other objects in addition to their outline, they open up a great field for research. Their use largely dispenses with the need for dissection, while the periodic radiographing of a growing plant or small animal opens up a field of great value to the naturalist.

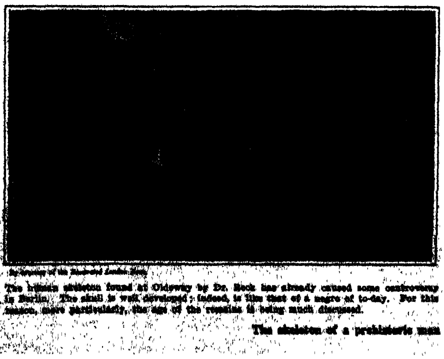
A Human Skeleton One Hundred and Fifty Thousand Years Old

DR. HANS RECK, of Berlin, has discovered, at Oldoway, in the north of German East Africa, the skeleton of a man who lived, in all probability, some 150,000 years ago. The photographs reproduced were supplied by the Doctor to the *Illustrated London News* and were accompanied by a note to the editor of that weekly. The following translation is from the German:

The rare animal fossils of the Tertiary Period yielded by Africa decided the Geological Palaeontological Institute and Museum of the University of Berlin to excavate the Oldoway "pit." In three months, some 1,700 bones were found and taken to the expedition's camp, there to be sheltered carefully under primitive, straw-roofed huts until they could be numbered, classified, and packed for their long journey. The huts in question were full of bones and huge relics of elephants. Most of the tusks discovered were surprisingly long, very light, and straight. The best was 3.8 meters (10 feet 5 inches) in length. Then there were represented the rhinoceros, the hippopotamus, numerous antelopes and gazelles, as well as pigs, rodents, and beasts of prey.

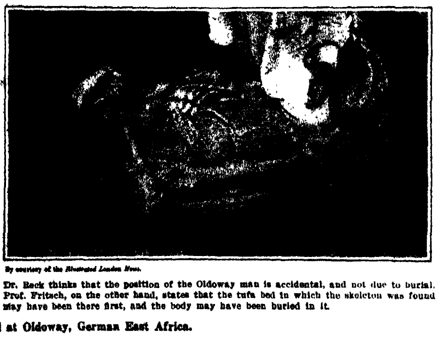
It was frequently difficult to obtain the bones. Not only was there a dearth of water and a blazing sun, but wild animals would arrive unexpectedly and disturb the diggers. Rhinoceroses, in particular, chased the men from time to time, sending them running through the trees and holding them prisoners for hours. The crumbling walls of the pit provided another obstacle. A precious relic would be seen in about the middle of the 50-foot wall, and those seeking it would have to be lowered by ropes, or rude ladders would have to be made and so set that the "find" could be reached. When, by good fortune, a place was found upon which a man could stand, the task was easier, for the natural "platform" could be enlarged by the pick.

One day brought with it a great surprise. On the steep incline of the "pit," the excavators found signs of a human skeleton, which was soon laid bare and protected by a straw roof. The discovery was seen to be of extreme age, and in a remarkably fine condition. The stratum about it was undisturbed, proof that it owed its position not to having been buried at the bottom of a hole dug down through several strata, but to having been contemporaneous with the stratum in which it rested. And that stratum is so old geologically that the skeleton must date at least from the Diluvial Period of Africa, which, it may be noted, synchronizes with the Ice Period of Northern Europe. No more precise date can be assigned to it until it has been compared with fossils found during the same excavations. It is typically negroid, and the first fossil human form found at Oldoway. The skull is highly developed, narrow and long; the head is set deep in the shoulders; the chest is massive. The position of the skeleton calls for notice. The legs were drawn up sharply, and obviously in a natural manner. This is additional argument in favor of the belief that the body was not buried; and must be taken in conjunction also with the facts that there are no traces of entombment, and that the contorted attitude is unknown in any case of burial by man. It would seem that the man was driven into the lake which was once above the spot on which his remains were found, or met with an accident on it, and was drowned. The body would be quickly covered with the mud at the bottom of the water and tufa, and so be protected from disturbing influences.



By courtesy of the Illustrated London News.

The human skeleton found at Oldoway by Dr. Reck has already caused some controversy in Berlin. The skull is well developed; indeed, is like that of a negro of to-day. For this reason, more particularly, the age of the remains is being much discussed.



By courtesy of the *Illustrated London News.*

Dr. Reck thinks that the position of the Oldoway man is accidental, and not due to burial. Prof. Fritsch, on the other hand, states that the tufa bed in which the skeleton was found may have been there first, and the body may have been buried in it.

The skeleton of a prehistoric man found at Oldoway, German East Africa.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

Road Construction by the "Penetration Method"

IN the "penetration method" of road construction a permanent foundation is first laid, after which large crushed stone is applied according to the road specifications A "hot road oiler" is then run over the road, applying a hot bituminous binder, which is forced into the layer of crushed stone under pressure, filling up the interstices between the stones, and holding them in place. As the binder hardens, the stones are held more firmly in place, forming a solid mass of crushed stone and bituminous material When the first course is finished, another layer of stone is rolled into place, the stones coming in contact with each other by the pressure of the steam roller, again a hot binder is applied by the "hot road oiler," filling up any crevices. In this way a solid road is obtained with no openings between the stones, and no moisture can get into the road and disturb its surface when it freezes, as is frequently the case in macadam roads The stones are gripped in the bituminous binder, and all spaces filled up, so that the stones cannot be picked out by automobile traffic Of course, a road of this type has no dust.

The machine here illustrated is specially constructed to deliver the hot bituminous binder under pressure. It is a 5½-ton truck, having sliding gear transmission with wide ranges of speed The main tank holds 750 gallons of binder The binder in the tank is heated by coils of pipe in the tank, which coils are filled with steam This steam is generated in the flash boiler at the rear of the truck. The boiler is fired by fuel oil, which is carried in a small tank on the right-hand side of the truck, and hence invisible in our illustration The steam from the boiler is also used to run a reciprocating "plunger type" air compressor The air pressure forces the binder in the large tank into the road. A second small tank on the right-hand side of the truck carries the water for the boiler The boiler is also provided with an air primer for starting the fire underneath the boiler

Suitable arrangements have been provided for straining the binder when it is taken from the tank, before reaching the distributing manifolds situated underneath the boiler at the end of the truck The operator is stationed at the rear of the truck, directly above the manifolds, so that he can control and regulate the application of the binder to the road. Provision is made for attaching a nozzle and hose to the distributing manifold and applying the oil locally by hand

It can readily be seen that a full range is reached for the application of binder, by varying the air-pressure on the tank, by opening and closing the manifold nozzles, by varying the temperature at which the binder is applied, and by running the truck at different speeds. Binder can be applied at the rate of from ¼ gallon per square yard to as much as 2 gallons per square yard

Machine for applying hot binders under pressure in road construction.

Marvelous Growth of the Motor Truck Industry

OF course we all know that the motor truck industry has shown a remarkable development in the past few years. There is plenty of evidence of this, not only on the streets of our large cities, but on the country highways. Nevertheless, we believe that a picture of this growth will startle even the most observant man.

According to statistics published in the *Power Wagon*, there were, in 1910, 11,000 commercial motor vehicles. The next year the number had grown to 20,000. Thereafter the figures more than doubled each year. The year 1912 ended with 45,000 motor trucks, and last year the final figure rose to 95,000.

This geometrical progression cannot go on forever or in the next few years there would be more commercial than pleasure vehicles in service, and another decade would find more motor trucks than people in the United States But as yet there appears to be no checking of the phenomenal growth So far 1914 appears to be holding its own Already the number has reached 125,000, and that for only a third of the year, viz., to May 1st.

We have endeavored to picture this remarkable increase by letting one vehicle represent ten thousand. Then the growth year by year is, roughly, as shown in the accompanying drawing. It will be noted that 1912, 1913, and 1914 have each half a truck to their credit that is not shown in the drawing.

Quoting again from *Power Wagon*, New York has 8,900 motor trucks in service, and Chicago 4,300, while third position is held by Los Angeles, which in three years has jumped from eighth position, with 800 trucks, to third position, with 4,000. Philadelphia holds fourth position with 3,000 motor trucks.

Most significant has been the progress in the use of "fleets" of trucks. There are now 149 concerns using 20 or more trucks, and of these twenty-two operate "fleets" of 100 or more. Among owners of five or more trucks department stores lead, with 2,758 machines; express companies come second, with 2,040 machines; and brewers third, with 1,543 machines. In actual numbers of trucks, furniture, hardware, and other trades lead, although they do not use as many trucks in fleets.

Pintsch Gas Residue for Motor Fuel

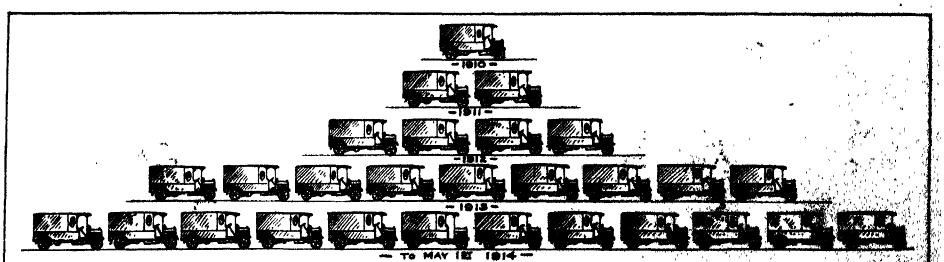
WHAT with the comparatively high price of gasoline anything that holds even the remote promise of taking the place of that commodity quite naturally is of interest to users of heavy motor vehicles, and in this connection the experience of a prominent gas company in Texas should prove doubly interesting, for the company has succeeded in using with its own vehicles a kind of fuel that never has been used before. The company in question is a large producer of Pintsch illuminating gas for residences and railroad trains and until very recently had considered it quite a problem to be rid of the great quantities of residue which accumulate. Previously, this residue, which is brownish in color and a hydro-carbon in nature, had been permitted to flow away and mingle with the waters of a large river. Now, however, a way has been found not only to use the residue, but to materially reduce the expense of operating the company's heavy trucks as well. The residue is passed through a small still and collected as a slightly lighter and colorless liquid. This liquid then is mixed with half its volume of commercial petroleum, the resultant compound costing the company all told 11 cents a gallon. In using the compound the ordinary gasoline carbureter is used and no need has been found for making adjustments of either fuel or air supply. Some slight carbonization results from the use of the fuel, but as this is a light, flaky deposit, it is of small consequence and blows away easily through the exhaust pipes. In starting during cold weather slight difficulty also is experienced by the drivers, though this is overcome by "spinning" the motor rapidly. It is stated that the company not only uses the new fuel itself for all of its vehicles, thus effecting a material economy in operating expenses, and, incidentally, obtaining considerably more power, due to the greater number of heat units contained in the fuel, but that it is producing it in limited quantities for the use of others. It is expected that other producers of Pintsch gas also will make some attempt to turn their unprofitable residue into profit as a result of the experiment of the Texas company.

Motor Truck Notes and Queries

L. G. V. writes: "What devices are there on the market intended to prevent the theft of a motor car or truck? Our delivery car is driven by one man who often has occasion to leave the machine standing for 15 or 20 minutes while he enters an apartment building to receive the day's orders. There have been several thefts of automobiles reported recently in our city, and as our car consists of a new chassis of the pleasure type with a panel body mounted thereon, it would make as valuable 'pickings' as would a high-grade touring car."

A. Nearly every new car is provided with a certain form of plug or lock and key that cuts off the ignition current. If a plug is ordinarily used, its place may be taken by a nail or cotter pin of the proper size, while the ordinary ignition lock is guarded only by a "blank" key or one that can be easily duplicated. Consequently, neither of these means is especially efficient against the experience of an automobile thief. Especially designed ignition locks are made, however, in which a famous type of burglar proof tumbler lock must be opened with

(Concluded on page 526.)



Motor trucks more than double their numbers each year. Each truck here represents ten thousand.

RECENTLY PATENTED INVENTIONS

[illegible] by special arrangement with the inventors. Terms on application to the Advertising Department of the Scientific American.

Pertaining to Apparel.

GARMENT.—B. I. Flegel, 416 E. 12th St., New York, N. Y. The invention has for its purpose the provision of a garment, such as a rain coat, cloak, and the like, and provided with a convertible collar and hood arranged to permit its use as an ornamental collar or as a hood, with or without a military effect.

GARMENT FORM.—H. T. Palmenberg, 710 Broadway, New York, N. Y. This inventor provides a form arranged to provide a cushion between the body and the stand, with a view to prevent the lower end of the body from striking the base of the stand, to the detriment of the body in case the fastening device for fastening the body to the stand is loosened.

Electrical Devices.

ELECTRIC LAMP SOCKET.—M. Reich, 311 W. 56th St., New York, N. Y. This improvement reduces the labor of installing an electric lamp socket; enables an operator to install the socket in service position; simplifies the construction and mounts the socket readily in service position.

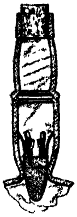
Of Interest to Farmers.

AUTOMATIC HEN MARKER.—F. H. Pebbles and K. D. Grant, 2230 S. 22nd St., Philadelphia, Pa. This invention provides a nest construction with devices whereby, when a hen enters the nest, a drop of ink or paint of any suitable nature will be caused to drop upon her back. By this means, the hens which enter nests will be marked, so as to clearly identify them and distinguish them from the hens which do not frequent the nests.

PICKER'S SACK.—A. H. Labrabee, Corona, Cal. The primary object here is to provide a top for a sack, which will keep sticks and trash from falling into the sack during the picking operation. An object is to provide a sack which is so constructed as to render it impossible for a picker to clip fruit directly into the sack, thereby injuring the fruit by the fall.

Of General Interest.

NON-REFILLABLE BOTTLE.—W. W. Smith, address Stanley S. Spencer, Darlington, Md. An object of this invention is to provide a receptacle for holding liquids from which the liquids may be readily poured, but into which the liquids cannot be readily returned after it is once emptied. The device is cheap to manufacture.



NON-REFILLABLE BOTTLE.

SEA-ANCHOR.—F. Rouse, 2702 Hyde St., San Francisco, Cal. This invention provides a spreading frame for an anchor adapted to maintain its operative position irrespective of added weight; provides a buoy for said anchor to maintain the equilibrium thereof; and provides oil and a ballasting compartment adapted to hold and distribute a liquid to affect the surface of the water in which the anchor is held when in service.

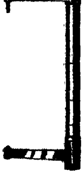
CALCULATOR OR ABACUS.—R. C. Bennett, care of A. P. Bennett, 144 W. 87th St., New York, N. Y. This invention refers to counting elements known as abaci, and has reference more particularly to the frame structure, which comprises a member carrying the counting elements and provided with supports at the ends of such a shape that the said member is in normal position at all positions of the supports.

SUPPORT FOR NOTE BOOKS AND THE LIKE.—J. Walker, Augusta Works, 19-21 Warstone Lane, Birmingham, England. The invention provides the frame which carries the book with means for preventing accidental turning-over of the leaves, with means for adjusting the same vertically and angularly in a horizontal direction, with means for adjusting the slope of the same, and with means, when it is used as a typewriter, for fixing it securely to the frame of any ordinary machine.

VENTILATOR.—J. A. Hosse, 3536 Sunnyside Ave., Falls of Schuylkill, Philadelphia, Pa. Mr. Hosse's invention relates to ventilators of the type used upon the tops of chimneys, flues, and the like, for the double purpose of preventing entrance of rain water into the chimney and of affording ready means for the escape of smoke from the chimney, while at the same time adding an ornamental appearance to the chimney top.

Hardware and Tools.

MICROMETER CALIPER.—E. W. Marion, 1832 Butler St., Philadelphia, Pa. This improvement has reference more particularly to a device which comprises a pair of relatively adjustable heads provided with measuring points, and means between the heads for altering the normal fixed distance between them. It provides a caliper with which measurements from zero to any number and fractional part of standard units, as machine practice may require, can be made by a simple adjustment of the parts.



MICROMETER CALIPER.

Household Utilities.

UTENSIL KNOB.—E. C. Fritz and E. C. Anderson, Somerset, Wis. Address the former, Somerset St., Croix Co., Somerset, Wis. The invention relates to knobs for use with cooking utensils and the like, and refers more particularly to a device which comprises a knob proper, fashioned from an elongated spirally-disposed member, and means for attaching said member directly to the utensil or body

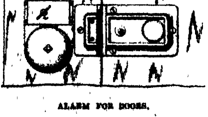
Machines and Mechanical Devices.

ALARM WATCH.—J. S. DeWitt, 306 N. Arthur St., Pocatello, Idaho. The more particular purpose here is to provide a watch with means for mounting it upon a person's wrist or ankle and providing said watch with additional means for producing a gripping or squeezing effect upon the wrist or ankle, for the purpose of attracting the attention of the wearer, and thus serving the purpose of an alarm.

APPARATUS FOR MANUFACTURING ICE.—L. C. Bond, Box 241, Beaufort, Charleston, S. C. This invention provides an apparatus whereby clean ice can be manufactured from water containing impurities in suspension. This is attained by providing moving receptacles adapted to receive the water to be frozen and positioned in the brine tank, the temperature of the brine being maintained below the freezing temperature of the water.

MATRIX MARKING MACHINE.—W. A. Heidel, 427 Jackson St., Mankato, Minn This invention provides for recording matter to be printed and preserving a paper record of such matter, to be used as a matrix from which slugs may be made; simplifies the type bar mechanism so that a number of independent type bars may be lowered to different levels, each type bar carrying a plurality of type, the parts so arranged that the letters to be printed in a line are brought together by virtue of the levels of the several type bars; provides mechanism for restoring the type bars to a predetermined level; provides for properly alining and clamping type to enable them to make an impression in the printing of a line, and improves the mechanism for holding the type characters in position for making impressions. The machine may be produced at a very nominal cost.

ALARM.—J. Richman, 570 Ralph Ave., Brooklyn, N. Y. This alarm is more especially designed for use on doors and arranged to sound an alarm when a person pushes the locked door. For this purpose use is made of an alarm device provided with an escapement wheel and an escapement lever, and a locking and releasing device for the said lever to normally lock the same against movement, the said locking and releasing device being adapted to be engaged by the door bolt when the latter is in closed position.



ALARM FOR DOORS.

HOOD FOR TYPE WRITING MACHINES AND THE LIKE.—M. W. Potter, Red Lodge, Mont. This invention relates to a collapsible hood to constitute a protective cover for typewriting machines and the like, and particularly to a hood comprising a flexible covering, and a framework including a series of separate foldable bows to maintain the cover in distended form, or to collapse the cover.

CRULLER SHAPING MACHINE.—I. Heine, 553 W. 48th St., Manhattan, N. Y., N. Y. The object here is to provide a machine which will automatically shape dough fed into the machine in a predetermined shape, as, for example, a cruller, and deliver the shaped dough, further, in shaping the dough by the machine, all waste of dough is eliminated.

STOP MOTION.—K. Bloat, care of Scranton Silk Machine Company, Scranton, Pa. An improved stop motion is provided by this invention for use on reeling machines to stop positively and quickly the reel in case of the breaking of a thread or yarn or the running out of the yarn from its spool. The device requires no fine adjustment or sensitive balancing by skilled workmen, and the parts are prevented from being actuated by mere vibration incident to the running of the machine.

Railways and Their Accessories.

RAILWAY CAR.—J. W. Spaur, care of Emmet Carey, Philipsburg, Mont. This inventor provides a construction of cars whereby the car ends will be disposed at an oblique angle transversely of the track, and hence upon a collision, the cars will not tend to telescope with the ordinary form of car, but by reason of the car ends being disposed in substantially parallel relation and obliquely with respect to the track, will tend to be thrown to one side of each other as they come together by impact of collision.

SWITCH LOCK.—J D Moore, Folkston, Ga The purpose here is to provide an arrangement which will effectively hold the switch point against the main rail and which may be readily released when it is desired to open the switch by connections of such character as that they may be actuated when the switch throwing lever is raised

AUTOMATIC WHISTLE.—G. R. Dunn, R F. D. No. 6, Elkhart, Ind. This invention provides means which may be disposed alongside the track for operating the whistle independently of any attention on the engineer's part It provides means for automatically operating a whistle which may be disposed at predetermined points, so as to insure the sounding of the whistle at these points.

Pertaining to Vehicles.

AMBULANCE AUTOMOBILE—F. E Campbell, 241 W. 23rd St., New York, N. Y. This invention provides means for, at will, converting an automobile of usual construction to adapt the same for use as an ambulance; provides an ambulance which may be arranged for the introduction of a stretcher without forcing the persons carrying it to step into the street, provides means whereby patient and stretcher may be introduced sidewise into an automobile, and thence moved across the body to provide a passageway for passengers entering the same side of the automobile, provides an extension to the automobile body for holding a portion of the person of a patient; and provides means over which the stretcher may be moved in depositing the same within the automobile body.

LOCKING DEVICE FOR AUTOMOBILES—J. J Meyer, 306 Lenox Ave, New York, N Y An object here is to provide a device for automobiles to prevent theft thereof by preventing unauthorized persons from running the automobile A further object is to provide a device which can be readily carried about and easily applied, even in the dark

SIGN—L Gottscholl, 462 Broadway, New York, N. Y This sign is for use on automobiles and the like to display a license number or other distinguishing marks which can be distinctly read, which are visible at night for a great distance, and which greatly aid the eye in detecting the number of distinguishing marks as well as aiding the memory in remembering the same.

MANURE CATCHER. C H Ferguson, 66 Lafayette St., Jersey City, N J This catcher is of the type adapted to be applied to horses while being driven through city streets, so as to prevent the dropping of manure in the streets, with the expense to the municipalities of cleaning the streets. It prevents the spread of diseases by manure dust in windy weather

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY You will find inquiries for certain classes of articles numbered in consecutive order If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information There is no charge for this service. *In every case it is necessary to give the number of the inquiry* Where manufacturers do not respond promptly the inquiry *may* be repeated

Munn & Co Inc

Inquiry No 9362 Wanted the name and address of the makers of a machine for splicing ties

Inquiry No 9363 Wanted the names and addresses of manufacturers of machinery for printing on intaglio copper plates

Inquiry No 9364 Wanted the name and address of buyer of mica in a crude state

Inquiry No 9365 Wanted the name and address of a manufacturer of machinery for embossing tin foil as is used in packing cigarettes

Inquiry No. 9366 Wanted the name and address of a manufacturer of wire wheels front axles complete with steering or separate, light sheet metal bodies, fuel tanks with cocks pressed steel frames, mufflers, motors of the two-cylinder opposed type cushions and many smaller parts for cycle cars

Inquiry No 9367 Wanted the name and address of a manufacturer of an automatic centering machine

Inquiry No 9368 Wanted, the name and address of glass-bottle manufacturers or glass blowers who can manufacture a glass bottle and perforate it with some 12 small holes in large quantities for export to sell at a popular price

Inquiry No 9369 Wanted the names and addresses of users of Indian Steatite (Soapstone) Corundum and other Indian minerals in quantities

Inquiry No 9370 Wanted the names and addresses of manufacturers of small wooden articles particularly in such soft woods as pine and fir for articles such as toys furniture, etc

Inquiry No 9371 Information wanted where one could buy or have made to order machine to be used for making solid back brushes

Inquiry No 9372 Wanted the name and address of manufacturers of a collapsible box about 12 inches square It must be strongly made to withstand rough usage in transit

Inquiry No 9373 Wanted the name and address of a manufacturer of machinery that will make twine out of scrap paper

Inquiry No 9374 Wanted the name and address of manufacturers of a powder paste which, when mixed with cold water will make a white paste suitable for papering, costing no more than 4 cents per pound in ton lots

Inquiry No 9375 Wanted the name and address of the manufacturer of a separable fastener invented especially for shoes and other articles

Inquiry No 9376 Wanted the name and address of a manufacturer making clock-work mechanism for running window display machines as employed by safety razor manufacture

Inquiry No. 9377 Wanted, the names and addresses of factories making farm implements for export

Inquiry No 9378 Wanted, the name and address of a manufacturer of smooth metal mirror frames, such as are sold in 5 and 10 cent stores with a mirror and a cardboard back.

Inquiry No. 9379 Wanted, meteorites - information desired concerning available specimens.

Inquiry No 9380 Wanted the name and address of a manufacturer of burners and handles for gas-heated sad iron

Inquiry No. 9381 Wanted the name and address of manufacturers of vacuum adhesive hangers or other appliances for hanging cards, frames, charts, etc., to walls of buildings.

Motor Truck Notes and Queries

(*Concluded from page 524.*)

the proper key before the current can be turned on. Locks of a similar nature are also provided to be installed in the fuel line. A third class of thief-proof automobile locks is intended to be placed in the gear-shift slot so that the transmission cannot be moved out of the neutral notch. It will be observed that all of these locks are designed solely to prevent the car from being moved under its own power, and it is hardly probable that the thief would take the machine in tow. Locks of this nature may be used on the car when it is stored in a public garage, for the truck can then be moved about by hand to make room for other machines, and yet it cannot be run under its own power without the owner's knowledge.

W. L. K. writes: "I remember the announcement of the manufacturer of a half-ton truck to the effect that his machine had hauled six or seven tons. As I understand that overloading is a practice universally condemned by reputable truck manufacturers, I should think such an announcement would do more harm than good to the industry in general."

A. If the conditions were exactly such as those cited, you are correct in assuming that great harm would be wrought to the truck industry. The load to which you refer was not carried directly on the half-ton truck, however, but was pulled, or hauled, by it in much the same manner as a locomotive draws a train of loaded freight cars. By the use of properly-designed trailers, a small truck may be made to do the work of several cars on a smooth level road, and the strain on the tires, springs, motor, and mechanism in general will be no greater than would be the case were a normal load to be hauled up a hill. A portion of the load should be carried on the truck in order that sufficient traction will be furnished to the wheels so that they will not slip. A truck used in this manner is known as a tractor, while the trailer may be any form of vehicle not propelled by its own power. Special types of trailers have been manufactured to be used in connection with some of the low-priced pleasure cars so that the latter may be easily converted into efficient commercial vehicles.

P. J. N. writes: "An ordinance has recently been passed in our town prohibiting the use of the muffler cutout on motor vehicles. The man who drives our 3-ton truck uses the cutout almost constantly, and tells us that it is necessary in order to give him sufficient power for some of the steep hills. What shall we do if this proposed ordinance is enforced?"

A. It is probable that the driver of your truck shares the popular "superstition" to the effect that eliminating the muffler greatly increases the power developed by the motor. Tests have shown that, in certain instances, a poorly-designed muffler may absorb from 10 to 15 per cent of the power developed by the motor, but that this is only when the engine is working at its full capacity, and that, therefore, the cutout is never really necessary except when the car may be climbing a hill so steep that every ounce of energy is required from it. But the low gear is designed to furnish the proper reduction so that any hill may be climbed without the use of the cutout, and, therefore, its use must be an admission that the motor is in poor condition. We would suggest that you overhaul your motor thoroughly, clean the valves, remove the carbon, and, if necessary, install a larger and more efficient muffler.

The Challenger, "Shamrock IV," Under Sail

(*Concluded from page 530.*)

surface is not any larger in "Shamrock IV" than it is in the older boat.

It is stated that she has shown herself to be very stiff, too much so, in fact, for her own good when the airs are light. The centerboard is to be unshipped, and a recent dispatch says that about five tons of lead is to be taken from the keel. These changes, together with the double

TOOLS

We have studied the tool question very carefully and we believe that every one of

Goodell-Pratt's

tools is built on correct mechanical principles; that it is built of materials which will give the longest wear; that the price at which it is sold represents the greatest possible value.

We not only make tools for all trades, but also a number of useful household articles. They are all of the same high quality: well made, well finished and nicely packed, so that they reach you in first-class condition.

[illegible] rig, should improve her average speed over a triangular course under light weather conditions. Furthermore, the removal of the steel centerboard and five tons of lead should reduce the draft of the "Shamrock" from 1½ to 1¾ inches. This, because of her shoal body, should shorten the water-line length by over a foot and reduce her time penalty.

Among our illustrations, the most interesting is that showing the method of stiffening the lofty, hollow, wooden mast of "Shamrock IV," the novelty consisting in a five-strut trussing, which is applied to the mainmast at about two thirds of its height, two of the struts extending athwartship, one projecting forward, and the other two at angles of 45 degrees. The "Shamrock" has been tried in strong winds, and is said to carry her lofty rig without any signs of weakness.

Saving Men from Submarines

(Concluded from page 516.)

siren is a plate covering a telephone transmitter, which can be broken by the rescue party, and communication thus established with the men imprisoned below. If the salvage operations are likely to take some time, arrangements can be made for passing liquid food down the air-pipe, as has been done in the case of miners buried alive under a fall of earth, but with whom communication has been established pending their being dug out. The inventor maintains, however, if his ideas are properly carried out, the crew would be able to stay at the bottom for a very considerable time, as the lockers under the seat in the cylinder are supposed to be kept stocked with provisions, in readiness for such an emergency, and there is a tank which is to be kept filled with fresh water. In one locker there is an electric battery, to give light to the imprisoned men, and in another is compressed oxygen, in case of need. There is also an inner chamber round the boat, filled with compressed ordinary air, which can be used if required. Round the fresh-water tank is another tank, in which sea-water can be admitted by a valve, to be used as ballast, if necessary, and this tank is also to be used as a lavatory and a means of keeping the boat pure and clean—a very important consideration if life is to be maintained for any length of time.

Science and the Tariff

(Concluded from page 526.)

classification and assessment of customs duties on cotton yarn and cloth, due to variations in the atmospheric conditions, the Treasury Department has declared that "whenever the weight is found within 5 per cent of its given equivalent weight in the table it will be necessary to make further trials of at least four samples, and if the average weight is again found to be under 5 per cent, the sample must be conditioned; that is, dried to bone dryness, and a regain of 8½ per cent added back."

Bone dryness of the cotton yarn, or cloth, is a condition in which all moisture is expelled, and this is only accomplished by dryness to a constant weight in a circulating atmosphere at a temperature of 110 deg. Cent. The regain of 8½ per cent added to the bone-dry weight would give the weight of the cotton yarn, or cloth, as if it had been subjected to an atmospheric condition of about 70 deg. Fahr. temperature and 65 per cent relative humidity. The number of the yarn calculated on this weight would be the size of the yarn, provided it had been subjected for a sufficient period of time to these standard atmospheric conditions.

In order to determine accurately the bone-dry weight, the Treasury Department has recently installed in the U. S. Customs Laboratory, Appraiser's Warehouse, 641 Washington Street, New York, a type of a machine known as the Freas electric-conditioning oven. It is the second of its kind to be manufactured, the other one having been placed in the textile division of the Bureau of Standards in Washington.

The oven is built of heavy [illegible] asbestos [illegible] with chamber size 12 inches

[illegible]

For over three years French and German motorists have been getting from 10,000 to 15,000 miles out of their tires by "half-soling" them with Steel Studded Treads.

In eight months over 20,000 American motorists have followed their example and are saving $50.00 to $200.00 a year in tire expense.

We Ship On Approval without a cent deposit, prepay express and let you be the judge. Durable Treads double the life of your tires and are sold under a signed guarantee for 5,000 miles without puncture. Applied in your garage in 30 minutes.

Special Discount offered to motorists in new territory on first shipment direct from factory.

A postal will get full information and sample within a week. State size of tires. Don't wait—write today.

PIERCE-ARROW

The stomach that calls attention to itself is not a good stomach. The servant who requires your instruction is not serving. The greatest attribute a motor car can have is unobtrusiveness. Service comes first, the service that you can lean upon, that requires neither adjustment nor allowance in your plans.

G.V. Electric Industrial Trucks

Here are two G. V. Electric freight trucks moving fertilizer at the great plant of the F. S. Royster Guano Company at Norfolk. Others are used by the American Agricultural Chemical Company.

Nearly 300 are used by such firms as the National Cash Register Company, Pacific Mills, Fall River Line, Brown & Sharpe Mfg. Company, Erie Railroad, Lackawanna Railroad, etc., etc.

One thousand tons of slate have been moved in 24 hours with one of these little trucks. The saving and labor is almost unbelievable.

We build the strongest machine of this type ever produced. We anticipate abuse and hard work. Everything is simple, all mechanical parts accessible. Single reduction gearing—no chains.

Write us for special set of literature 101-F.

"A Man Would Die in the First Alcove"—

"There are 850,000 volumes in the Imperial Library at Paris," said Emerson. "If a man were to read industriously from dawn to dark for sixty years, he would die in the first alcove."

And he would not die a *well-read man.*

But if a man could know what few great books are enduringly worth while and could read those few—Histories, Biographies, Dramas, works of Travel, Fiction, Philosophy, and Poetry—he would become well read, even though he could devote to them but a few pleasure moments a day.

Sixty-seven of the world's greatest authorities—a Supreme Court on books—united in selecting the few books that will live forever; these few are known as

THE FAMOUS FIVE-FOOT SHELF OF BOOKS

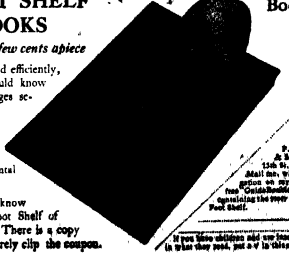
418 masterpieces at a few cents apiece

Any man who cares to read efficiently, instead of wastefully, should know what few books these judges selected, and why.

He should know why 100,000 successful men are finding in the Five-Foot Shelf just the mental stimulus they need.

Everything you need to know about the famous Five-Foot Shelf of Books is in a *free* booklet. There is a copy for you—no obligation; merely clip the coupon.

Be Guided by This FREE Booklet



S. A.
6-27-14
P. F. Collier & Son, 416 W. 13th St., N.Y. City
Mail me, without obligation on my part, your free "Guide Booklet to Books" containing the story of the Five-Foot Shelf.

If you have children and are interested in what they read, put a ✓ in this square. ☐

by 12 inches by 12 inches. The frame of the door is made of heavy aluminum casting insulated with asbestos, and is provided with a double window (mica on the inside and glass on the outside) with drop shield, which permits of inspection of the oven without opening the door. Two small electric lights are placed in the upper inside corners of the chamber, and can be turned on or off by a switch-button on the front of the oven above the door. One of the lights is continuous, and serves as a source of illumination for the oven, and the other is intermittent, and indicates the making and breaking of the contact of the heat regulator.

To expedite the drying, the circulation of heated air supplied to the oven is artificially adjusted by means of a fan situated in the back of the chamber, and driven by a 1/15 horse-power motor, shunt wound, with a speed of 1,100, and a voltage of 110. Complete ventilation, to get rid of the moisture from the substance being dried, is obtained by two openings, or vents, one on each side of the back of the oven next to the bottom; these openings can be closed, or partially closed, by means of metal plates which fit over the openings, and are readily turned.

The heating element, which is wound with a high heat-resisting wire, is situated in the bottom of the chamber underneath a fire-clay plate which contains numerous holes for transmission of heat. The regulation device is fitted in a separate compartment made entirely of metal, and located above the chamber. Its action depends on the expansion of the metal tube through the chamber, operating a lever, which makes and breaks a contact, with proper means to prevent arcing. The lever is extended to serve as an indicator, operating up and down a graduated scale on the outside of the oven. The indicator is moved to the desired temperature by simply turning the knob screw at the bottom of the scale.

The oven is also provided with a double window (mica on inside and glass on outside), with drop shield, on the side of the oven, so as to permit operator to manipulate the horizontal rod with fastened hook for removing and returning baskets from carrier to connecting rod attached to one arm of the balance.

To the top of the chamber is fastened a four-armed horizontal metal frame. At the end of each arm is attached a small pulley, and on these pulleys moves an endless chain, similar to a bicycle chain. This chain is moved by a toothed wheel on the side of the chamber, which, in turn, is moved by a thumb-screw on the outside of the oven. Ten metal hooks are suspended from the chain, and to these are swung ten metal mesh baskets, each of which is 6 centimeters in depth by 4 centimeters in diameter. By the aid of the thumb-screw, the carrier can be turned, so as to bring the baskets into position under the balance to be weighed within the oven.

On top of the oven is an analytical balance of 100 grammes capacity and 1/10 milligramme sensibility, one arm of which is attached to a connecting rod which passes through an orifice into the oven. By turning the horizontal rod which traverses the rear of the chamber, the baskets can be removed from the carrier and attached to the connecting rod which passes into the balance. By moving the carrier the baskets can consecutively be brought in position and attached to the connecting rod. All the baskets are adjusted so that they weigh the same, and are equal to the counterpoise which is suspended from the other arm of the balance.

In the conditioning of the samples of yarns and fabrics weighing 1,000 grains and less, this oven possesses the following features that are superior to other conditioning ovens, both electric and gas, that are now used in the textile trade: (1) It occupies a small space, about three feet square; (2) a constant temperature within 1 deg. Cent. can be maintained; (3) ten samples can be conditioned at one time; (4) an analytical balance, with a maximum load of 100 grammes and 1/10 milligramme sensibility, can be used for weighing the samples within the oven.
